

Polar bears hold key to understanding health risk of environmental pollutants

September 30 2005

Polar bears and people, at the chilly top of the Arctic's food chain, risk consuming a smorgasbord of industrial pollutants that have seeped into their habitat and pose potential health hazards.

Now a University of Florida researcher, aiming to better understand just how dangerous the chemicals might be to humans, has zeroed in on how effectively polar bears are able to rid themselves of environmental toxins consumed in the food they eat. It turns out the bears can completely eliminate only one of five of the classes of industrial contaminants they are exposed to, a finding that's bad news for the bears and other species who share their environment, according to Margaret James, Ph.D., an environmental toxicologist at UF.

"The polar bear has quite an efficient system for metabolizing these pollutants," said James, adding "If they can't do it, then it's unlikely that other animals or persons can."

The UF study, published this month in the journal *Drug Metabolism and Disposition*, could help researchers learn more about the effects of pollutants on humans living in the Arctic who share the same staple diet as the bears.

James, chairwoman of the department of medicinal chemistry at UF's College of Pharmacy, became interested in studying pollutants nearly 30 years ago. That was when researchers first began to understand that industrial byproducts were carried to the Arctic by trade winds and then

settled in the subzero temperatures, incapable of re-entering the atmosphere and making them more likely to accumulate in the food chain.

Then in the 1980s and 90s, Canadian and Scandinavian scientists showed that the bodies of polar bears contained high levels of industrial pollutants. Learning more about the extent to which the bears could break down and eliminate the chemicals dovetailed with James' expertise in how the body metabolizes drugs.

“There is no difference to the body in metabolizing a drug or a pollutant,” she said. “The process is the same.”

In her research, James concentrated on five types of chemical contaminants known by the acronym POP, for persistent organic pollutants. They include compounds produced by a burning process; a compound used as a substitute for the pesticide DDT when it was banned, and which itself was subsequently banned in 2004; TCPM, an industrial compound found in the Arctic but of unknown origin and toxicity; PCP, used as a wood preservative; and PCBs, industrial chemicals used for many years in electrical applications. All of these substances, with the exception of TCPM, are regulated or banned, but they persist in the environment.

Polar bears break down these fat-soluble chemicals in two steps, each of which makes the substances more water-soluble and therefore easier to excrete, said James. The first step, however, results in a compound that is more chemically reactive and therefore more harmful to living cells, with the potential for reproductive or neurological damage. The second phase, often slower than the first, determines how successfully the animals eliminate the toxins, she said.

Studying liver tissue samples obtained from the bears, James found that

the animals were surprisingly efficient at metabolizing one of the types of industrial chemicals studied – those produced by a burning process, which are similar to the compounds that form when meat is cooked on a grill. The other pollutants, she determined, could not be fully excreted.

“This suggests that other species will metabolize the pollutants more slowly,” said James. “When they are not sufficiently excreted the levels go up.”

One obstacle James faced in her research quest: how a Florida researcher might obtain a polar bear for scientific study. Her break came in 2003, when Canadian colleagues Stelvio Bandiera, Ph.D., professor of biomolecular and pharmaceutical chemistry at the University of British Columbia in Vancouver, and Robert Letcher, Ph.D., at Environment Canada in Ottawa, donated liver tissue samples from three adult male bears to UF. The bears were from a legally controlled hunt in 1993 by the Inuit people native to the Canadian Arctic.

Bandiera began his research in Canada 15 years ago looking at the effects of pollutants on great blue herons, seals and other animals living in marine environments. His research then shifted to arctic mammals about 10 years ago, when he first examined liver tissue from polar bears. His studies to date focused only on the first phase of the metabolic process.

“We believe that the polar bear is one of few species able to metabolize these pollutants. We think it is likely that humans may also have this ability, but this is not yet known,” Bandiera said.

He added that because polar bears are mammals with a diet similar to the native Inuit, they may serve as good surrogates for studying human populations also exposed to the pollutants.

In 2001, the world population of polar bears was estimated to be between 21,500 and 25,000, of which some 15,000 were in Canada. James said experts have observed a worldwide decline in their population, which some blame on environmental pollution.

James said her immediate research goal is to help scientists gain a better understanding of exactly how these compounds are eliminated from the body. People throughout the world continue to be exposed to chemical pollutants long after they are created and released into the atmosphere. Her long-range goal is to provide governments and regulatory agencies with scientific findings regarding the safety or potential risks of the environmental chemical pollutants that will guide future decisions about the use and the disposal of these compounds.
