

Bioethanol's impact on water supply 3 times higher than once thought

August 5 2009

Production of bioethanol may consume up to three times more water than previously thought, scientists are reporting. Credit: American Chemical Society

At a time when water supplies are scarce in many areas of the United States, scientists in Minnesota are reporting that production of bioethanol — often regarded as the clean-burning energy source of the future — may consume up to three times more water than previously thought. Their study appeared in ACS' journal *Environmental Science & Technology*.

Sangwon Suh and colleagues point out in the study that annual [bioethanol](#) production in the U.S. is currently about 9 billion gallons and note that experts expect it to increase in the near future. The growing demand for bioethanol, particularly corn-based [ethanol](#), has sparked significant concerns among researchers about its impact on [water](#) availability.

Previous studies estimated that a gallon of corn-based bioethanol requires the use of 263 to 784 gallons of water from the farm to the fuel pump. But these estimates failed to account for widely varied regional irrigation practices, the scientists say.

The scientists made a new estimate of bioethanol's impact on the water supply using detailed irrigation data from 41 states. They found that bioethanol's water requirements can be as high as 861 billion gallons of water from the corn field to the fuel pump in 2007. And a gallon of ethanol may require up to over 2,100 gallons of water from farm to fuel pump, depending on the regional irrigation practice in growing corn. However, a dozen states in the Corn Belt consume less than 100 gallons of water per gallon of ethanol, making them better suited for ethanol production.

"The results highlight the need to take regional specifics into account when implementing biofuel mandates," the article notes.
