

New instrument keeps an 'eye' on nanoparticles

March 6 2011

This is a scanning electron microscope image of polystyrene nanoparticles. These particles are roughly 100 nanometers in diameter, and are readily detected with the analyzer. The uniform size distribution is used to calibrate the instrument. Credit: J.L. Fraikin and A.N. Cleland, UCSB

Precision measurement in the world of nanoparticles has now become a possibility, thanks to scientists at UC Santa Barbara.

The UCSB research team has developed a new instrument capable of detecting individual [nanoparticles](#) with diameters as small as a few tens of nanometers. The study will be published on line this week by *Nature Nanotechnology*, and appear in the April print issue of the journal.

"This device opens up a wide range of potential applications in nanoparticle analysis," said Jean-Luc Fraikin, the lead author on the

study. "Applications in water analysis, pharmaceutical development, and other biomedical areas are likely to be developed using this new technology." The instrument was developed in the lab of Andrew Cleland, professor of physics at UCSB, in collaboration with the group of Erkki Ruoslahti, Distinguished Professor, Sanford-Burnham Medical Research Institute at UCSB.

Fraikin is presently a postdoctoral associate in the Marth Lab at the Sanford-Burnham Medical Research Institute's Center for [Nanomedicine](#), and in the Soh Lab in the Department of Mechanical Engineering at UC Santa Barbara.

This is an optical microscope image of the microfluidic channel (light pattern) and sensing electrode (gold) of the analyzer. Nanoparticles are suspended in a fluid flow through the channel, and are detected individually as they pass through the sensing volume. Credit: J.L. Fraikin and A.N. Cleland, UCSB

The device detects the tiny particles, suspended in fluid, as they flow one by one through the instrument at rates estimated to be as high as half a million particles per second. Fraikin compares the device to a nanoscale turnstile, which can count — and measure — particles as they pass

individually through the electronic "eye" of the instrument.

The instrument measures the volume of each nanoparticle, allowing for very rapid and precise size analysis of complex mixtures. Additionally, the researchers showed that the instrument could detect bacterial virus particles, both in saline solution as well as in mouse blood plasma.
