

# NASA sees a 14-mile-wide eye and powerful Super Typhoon Songda

May 27 2011

---

This infrared image of Super Typhoon Songda was captured by the AIRS instrument on NASA's Aqua satellite on May 27, 2011, at 5:05 UTC (1:05 a.m. EDT). At this time, Songda was a Category 4 storm. The purple areas indicate very strong thunderstorms with heavy rainfall and there is a large area of them that surround the visible eye. Taiwan is northwest of the storm. Credit: NASA/JPL, Ed Olsen

Typhoon Songda became a Super Typhoon in the evening on May 26, 2011 (Eastern Daylight Time) as it reached a Category 5 status on the Saffir-Simpson Scale. NASA satellite data shows that the monster storm with a 14 mile-wide eye has weakened due to adverse wind conditions today and is still a powerful Category 4 typhoon.

The Atmospheric Infrared Sounder (AIRS) instrument on NASA's Aqua

satellite captured an infrared image of Super Typhoon Songda on May 27, 2011 at 5:05 UTC (1:05 a.m. EDT). At that time Songda was a Category 4 storm. The [infrared image](#) showed a large area of very strong thunderstorms with heavy rainfall surrounding the eye of the storm. The eye is almost 14 miles (12 nm/22 km) in diameter and those thunderstorms were dropping rainfall as much as 2 inches (50 mm) per hour.

On May 27 at 1500 UTC (11 a.m. EDT), Typhoon Songda's [maximum sustained winds](#) were near 125 knots (143 mph/231 kmh) down from its peak of 140 knots (161 mph/260 kmh) which it reached late on May 26. Songda has tracked north-northwest but is expected to turn to the north-northeast.

AIRS infrared imagery from today shows that the [cloud tops](#) are warming, and convection (rapidly rising air that forms the thunderstorms that power a tropical cyclone) is weakening. The rule with [infrared imagery](#) and thunderstorms is: the colder the cloud top, the stronger the convection and stronger the thunderstorm. So, what's making Songda weaken? Cooler [sea surface temperatures](#) (now that its north of 20 degrees north latitude) and increasing southwesterly vertical wind shear.

Taiwan is already feeling the effects from Songda as the surf has kicked up and is expected to remain rough until Songda passes this weekend. Songda is currently expected to pass just to the east of Ishigakijima island and to the west of Kadena Air Base, putting the island on the strongest side (the northeastern corner) of the storm. Songda is then forecast by the Joint Typhoon Warning Center to continue moving northeast and curving past the east coast of Japan, while its center remains at sea. By May 30, Songda is expected to have passed Japan.
