

Nanostructured electrodes for rechargeable sodium-Ion batteries

February 13 2012

The electrostatic attraction of electrochemically altered V₂O₅ layers provides a strong driving force for Na⁺.

Highly efficient 3V cathodes for rechargeable sodium-ion batteries have been developed by users from Argonne National Laboratory's Materials Science, Chemical Sciences & Engineering, and X-ray Sciences

Divisions, as well as the University of Chicago, together with the Center for Nanoscale Materials NanoBio Interfaces Group. With a near-theoretical capacity of 250 mAh/g, excellent rate capability and cycle life, and high energy and power densities of 760 Wh/kg and 1200 W/kg, respectively, these bilayered V_2O_5 systems can be used in applications at ambient temperature.

Rechargeable [battery](#) systems with transport ions other than lithium offer an alternative to lithium-ion batteries that would substantially expand the existing energy storage market, which is primarily based on lithium-ion technology. Sodium-based batteries are particularly attractive: Sodium is a cheap, nontoxic, and abundant element that is uniformly distributed around the world and therefore would be ideal as a transport ion for rechargeable batteries.

This research team's approach to achieving sodium ion intercalation was to use nanoscale materials that have two-dimensional layered structures with adjustable interlayer spacings capable of accommodating large volume changes. Ex situ and in situ synchrotron characterization studies revealed that sodium ion uptake induces organization of the overall vanadia structure together with appearance of long-range order between the layers. Upon deintercalation of sodium, the long-range order is lost while the intralayer structure is still preserved. Inducing ordering of nanomaterials in operando has thus allowed the realization of the highest possible electrode capacity by optimizing the balance of electrostatic forces. Improved elasticity and exceptional long-term stability of this open framework structure makes bilayered V_2O_5 a suitable cathode material for high-energy density rechargeable [sodium](#) batteries.
