

# Nanotechnology for solar energy conversion systems

May 25 2012

---

EU researchers extensively characterised the self-organisation of nanotubes and developed novel compositions particularly appropriate to solar energy conversion applications.

Self-organized one-dimensional (1D) oxide nanotube systems are a hot research topic of late given that their inherently high surface area-to-volume ratio produces interesting and useful properties.

In particular, over the last 20 years, ordered arrays of porous [titanium oxide](#) (TiO<sub>2</sub>), or TiO<sub>2</sub> nanotubes, achieved via electrochemical anodisation have been extensively studied. To date, TiO<sub>2</sub> is the only material suitable for use as a photocatalyst (substance using light energy to enhance chemical reactions) due to its [high efficiency](#) and stability, low cost and safety profile toward humans and the environment.

[European researchers](#) set out to prepare and characterise self-organised TiO<sub>2</sub> nanotubes with an ordered structure similar to that of porous aluminium oxide (Al<sub>2</sub>O<sub>3</sub>) and silicon (Si) nanotubes via funding of the 'Preparation, characterisation and application of self-organised titanium oxide - nanotubes' (TI- Nanotubes) project.

In particular, investigators sought to understand key parameters governing self-organisation of TiO<sub>2</sub> nanotubes, specifically those affecting tube dimensions, orientation and morphology. The ultimate goal was to develop novel functional and structural materials with superior performance characteristics to be used in [solar energy](#)

conversion systems such as dye-sensitised solar cells.

Self-ordering mechanisms of TiO<sub>2</sub> nanotubes were investigated via a plethora of surface analysis technologies including Rutherford backscattering spectrometry (RBS) and nuclear reaction analysis (NRA) for depth profiling.

The TI- Nanotubes consortium successfully produced TiO<sub>2</sub> nanotube arrays doped with silver (Ag) or iron (Fe) that exhibited enhanced photocatalytic activity important for solar energy conversion applications.

Commercial exploitation of TI- Nanotubes project results has the potential to enhance solar energy efficiency and use with important benefits for the EU economy, EU citizens and the planet.
