

Global water sustainability flows through natural and human challenges

August 9 2012

Many sections of the famous Yongdinghe River in Beijing have dried up due to decreased runoff, and many years of over-exploitation of surface water and groundwater. Vegetation and houses took over the riverbed. Credit: Wu Yang

Water's fate in China mirrors problems across the world: fouled, pushed far from its natural origins, squandered and exploited.

In this week's *Science* magazine, Jianguo "Jack" Liu, director of Michigan State University's Center for [Systems Integration](#) and Sustainability, and doctoral student Wu Yang look at lessons learned in [China](#) and management strategies that hold solutions for China – and across the world.

In their article "Water Sustainability for China and Beyond," Liu and

Yang outline China's water crisis and recent leapfrog investment in water conservancy, and suggest addressing complex human-nature interactions for long-term water supply and quality.

China's crisis is daunting, though not unique: Two-thirds of China's 669 cities have water shortages, more than 40 percent of its rivers are severely polluted, 80 percent of its lakes suffer from eutrophication – an over abundance of nutrients -- and about 300 million rural residents lack access to safe drinking water.

Water can unleash fury. Floods in Beijing on July 21 overwhelmed drainage systems, resulting in scores of deaths. Water shortages also may have contributed to recent massive power outages in India as rural farmers stressed a fragile grid by pumping water for irrigation during drought.

China has dedicated enormous resources – some \$635 billion worth -- which represents a quadrupling of investment in the next decade, mainly for engineering measures.

Many small rural hydropower stations have been built across China without environmental impact assessments. This river in the Sichuan Province almost dried up after the construction of a small hydropower station. Credit: Wu Yang,

There needs to be, Liu and Yang say, a big picture view of water beyond engineering measures.

"There is an inescapable complexity with water," Liu said. "When you generate energy, you need water; when you produce food, you need water. However, to provide more water, more energy and more land are needed, thus creating more challenges for energy and food production, which in turn use more water and pollute more water.

"In the end, goals are often contradictory to each other. Everybody wants something, but doesn't take a systems approach that is essential for us to see the whole picture."

Liu, who holds the Rachel Carson Chair in Sustainability, is a pioneer in using a holistic approach to address complex human-environmental challenges. Solutions, he says, come from looking at issues from multiple points of view at the same time. That's the way to avoid the unintended consequences that plague China's water, and a way to prevent a water crisis from becoming a water catastrophe.

In their article, they give suggestions to make the grand investment more effective and efficient, strategies that apply not only to China, but resonate on a global level. For example:

- Shore up laws and policies with cross-organizational coordination to clarify who is in charge, and who has enforcement powers.
- Get proactive., Evaluate initiatives, set performance criteria and engage the public in planning

- Use social science to strengthen long-term plans by predicting people's behaviors and taking values into account.
- Remember the world has become much smaller, and global connections such as trade and sharing of international rivers have great impacts on [water sustainability](#) and quality.

At the core, they say, is the understanding of complex human-nature interactions. Such understanding is key to achieve [water sustainability](#) in China and the rest of the world.
