

Mars scientist explains why NASA chose Gale Crater for new rover

August 2 2012

NASA's Mars Science Laboratory rover is set to land within the ellipse on the floor of Gale Crater on Mars. Gale is 96 miles (154 kilometers) in diameter and holds a layered mountain rising about 3 miles (5 km) above the crater floor.

NASA chose Gale Crater as a landing site for its Mars Science

Laboratory rover because the giant crater probably had conditions that may have once hosted life. The bottom layers near the crater floor "have minerals in them that form in water," says Philip Christensen, Regents' Professor of Geological Sciences in ASU's School of Earth and Space Exploration.

These minerals include clays, sulfates, and gypsum, he says, and they can give scientists valuable clues about the habitability of early Mars.

Says Christensen, "The current thought is that when this crater first formed some 3.5 to 4 billion years ago, maybe in the bottom of it there was a standing lake, maybe there was groundwater." In any case, he says, there was enough water to make sediments that are full of aqueous minerals. These are good places to look for evidence of Mars' [habitability](#), past or present.

Christensen's comments appear in an interview given to science reporter Pete Spotts for the Christian Science Monitor (Aug. 1, 2012). They provide background on NASA's decision to send the rover to Gale.

Dubbed Curiosity, the rover is scheduled to land on Aug. 5, at 10:31 p.m. Arizona time. The size of a Mini-Cooper car, the one-ton nuclear-powered rover is the biggest, heaviest, and most sophisticated spacecraft ever sent to Mars.
