

Computer scientists suggest new spin on origins of evolvability

April 26 2013

Scientists have long observed that species seem to have become increasingly capable of evolving in response to changes in the environment. But computer science researchers now say that the popular explanation of competition to survive in nature may not actually be necessary for evolvability to increase.

In a paper published this week in *PLOS ONE*, the researchers report that evolvability can increase over generations regardless of whether species are competing for food, habitat or other factors.

Using a simulated model they designed to mimic how organisms evolve, the researchers saw increasing evolvability even without competitive pressure.

"The explanation is that evolvable organisms separate themselves naturally from less evolvable organisms over time simply by becoming increasingly diverse," said Kenneth O. Stanley, an associate professor at the College of Engineering and Computer Science at the University of Central Florida. He co-wrote the paper about the study along with lead author Joel Lehman, a post-doctoral researcher at the University of Texas at Austin.

The finding could have implications for the origins of evolvability in many species.

"When new species appear in the future, they are most likely [descendants](#) of those that were evolvable in the past," Lehman said. "The result is that evolvable species accumulate over time even without [selective pressure](#)."

During the simulations, the team's simulated organisms became more evolvable without any pressure from other organisms out-competing them. The simulations were based on a conceptual algorithm.

"The algorithms used for the simulations are abstractly based on how [organisms](#) are evolved, but not on any particular real-life organism," explained Lehman.

The team's [hypothesis](#) is unique and is in contrast to most popular

theories for why evolvability increases.

"An important implication of this result is that traditional selective and adaptive explanations for [phenomena](#) such as increasing evolvability deserve more scrutiny and may turn out unnecessary in some cases," Stanley said.

Stanley is an associate professor at UCF. He has a bachelor's of science in engineering from the University of Pennsylvania and a doctorate in computer science from the University of Texas at Austin. He serves on the editorial boards of several journals. He has over 70 publications in competitive venues and has secured grants worth more than \$1 million. His works in artificial intelligence and evolutionary computation have been cited more than 4,000 times.

Lehman has a bachelor's degree in computer science from Ohio State University and a Ph.D. in computer science from UCF. He continues his research at the University of Texas at Austin and is teaching an undergraduate course in artificial intelligence.
