

# A step closer to developing new anti-influenza agents

September 5 2013

---

James Cook University scientists have developed a new tool that can be used to more rapidly discover and develop new generations of anti-influenza drugs.

Associate Professor Patrick Schaeffer is head of JCU's Supramolecular and Synthetic Biology Group, which is leading the work.

"Recently, a new promising compound called nucleozin was shown by several research groups to have potent anti-[influenza activity](#)," Associate Professor Schaeffer said.

"This compound acts by a new mode of action that is to aggregate the essential nucleoprotein resulting in [viral replication](#) arrest."

Associate Professor Schaeffer said to develop new, safe and effective anti-influenza drugs acting by this mechanism, millions of compounds like nucleozin will need to be screened and tested for activity.

"The JCU team has developed a new tool that will help speed-up this mammoth task," he said.

"The new screening assay involves a fluorescent nucleoprotein that had previously been engineered by the same group to help the development of a new diagnostic platform for the detection of [influenza](#) infections.

"The team will now turn their new screening assay into a high-

throughput screening platform and will then start screening libraries of [natural compounds](#) from tropical sources."

The work was funded by Queensland's Smart Futures Fund and has been recently published in the journal *The Analyst*.
