Scientists from the University of the Philippines, Los Baños have

discovered a new plant species with an unusual lifestyle—it eats nickel for a living—accumulating up to 18,000 ppm of the metal in its leaves without itself being poisoned, says Professor Edwino Fernando, lead author of the report. Such an amount is a hundred to a thousand times higher than in most other plants. The study was published in the open access journal *PhytoKeys*.

The new [species](#) is called *Rinorea niccolifera*, reflecting its ability to absorb nickel in very high amounts. Nickel hyperaccumulation is such a rare phenomenon with only about 0.5–1% of plant species native to nickel-rich soils having been recorded to exhibit the ability. Throughout the world, only about 450 species are known with this unusual trait, which is still a small proportion of the estimated 300,000 species of vascular plants.

The [new species](#), according to Dr Marilyn Quimado, one of the lead scientists of the research team, was discovered on the western part of Luzon Island in the Philippines, an area known for soils rich in heavy metals.

"Hyperaccumulator plants have great potentials for the development of green technologies, for example, 'phytoremediation' and 'phytomining'", explains Dr Augustine Doronila of the School of Chemistry, University of Melbourne, who is also co-author of the report.

Phytoremediation refers to the use of hyperaccumulator plants to remove heavy metals in contaminated soils. Phytomining, on the other hand, is the use of hyperaccumulator [plants](#) to grow and harvest in order to recover commercially valuable metals in plant shoots from metal-rich sites.
