

## 'Subirdia' author urges appreciation of birds that co-exist where we work, live, play

November 26 2014, by Sandra Hines

Surprisingly, the diversity of birds in suburban areas can be greater than in forested areas, according to John Marzluff's new book "[Welcome to Subirdia: Sharing Our Neighborhoods with Wrens, Robins, Woodpeckers, and Other Wildlife](#)" (Yale University Press, 303 pp., \$30). The UW professor of environmental and forest sciences answered

a few questions for UW Today.

**Q: Please explain the suburban birds you describe as "adapters" and "exploiters."**

A: Adapters are birds that take advantage of the new foods and nesting opportunities that exist in suburban settings. They include familiar birds like chickadees, goldfinches, Canada geese and red-tailed hawks. The abundance of adapters increases with development because they utilize edges that exist between the many distinct built and natural landscapes in our neighborhoods.

Exploiters are even more in tune with humanity than are the adapters. They often have "house" or "barn" in their name, such as barn swallow, barn owl and house finch. My favorite, the American crow, and the denizen of Costco parking lots, the Brewer's blackbird, are exploiters. Exploiters may attain dense populations, but some are declining as the last scruffy parts of today's cities are tidied up and the cracks and crevices in older homes are sealed. The house sparrow and jackdaw of Europe are two exploiters on the decline.

In many cases, adapters and exploiters can show us how natural selection fashions the birds that live among us. Blackcap warblers in Europe, for instance, are in the throes of speciation as some in the population are evolving new migratory routes and morphologies that enable them to exploit bird feeders in England.

Evolution of birds in our backyards tells me that humans, while often destructive, also have a creative hand in shaping [biological diversity](#).

**Q: What about the "avoiders"?**

A: In contrast, avoiders decline in the face of human action. To these species, our activities are as deadly as the meteors of the past. Avoiders require extensive natural habitat situated far from cities. A familiar local avoider is the [northern spotted owl](#), but even the small Pacific wren is an avoider. Many birds that annually migrate from the neotropics to breed in and around Seattle, such as western tanagers, black-throated grey warbler, and Wilson's warblers, are avoiders.

In the Northwest, there are many fewer avoiders than adapters, so bird

diversity is highest in suburban settings and declines as we move either closer to the city or farther from it. This pattern is common across the northern Europe, Asia and Australia.

However, avoiders dominate tropical forest communities, so in those hyper-diverse settings development is likely to steadily decrease diversity.

Understanding that local diversity is a careful balance of animals that seek and avoid people teaches us that urbanization is not the answer to our conservation prayers. Rather, learning to appreciate the animals that co-exist where we live, work and play can motivate us to make the sacrifices – setting aside distant lands – that avoiders require.

**Q: You're tweeting on @subirdiaabout wildlife in your suburban backyard in Snohomish County. What's the most fun thing this fall?**

A: What's not to enjoy about a mature bald eagle or rough-skinned newt in the yard? But I've certainly had the most fun with the newest addition to my yard – a male mountain beaver that was unwanted in his former abode and now has been successfully transplanted to my sword fern-encrusted hillside. I'll be following his progress throughout the winter.

**Q: How do you know Jack DeLap, the artist who illustrated the book?**

A: Jack is not only a talented artist, but also a scientist in my lab. Jack started at the UW the year I was hired. As part of an expansion of his fine arts degree, Jack was working on a second bachelor's degree in wildlife science. Since then he completed a master's at Colorado State University and then returned here to do doctoral work on the urban bird

community that he elegantly illustrated for Subirdia.

**Q: What are examples from your "Nature's 10 commandments"—the things animals would ask for if they could get our attention?**

A: All animals would appreciate it if we lessened our fascination for large, manicured, turf lawns. Reducing lawn size and replacing lawns with native (or even nonnative) shrubs would increase the ability of suburbs to support ground-nesting birds, small mammals, salamanders

and garter snakes.

Our birds would ask that we do two simple things: keep our cats inside – outdoor cats kill up to 3.7 billion birds per year in the U.S. alone – and make our large-paned glass windows more visible. This can be accomplished by adding UV-reflective stickers to windows.

The UW could make a great contribution to bird safety by making our windows visible and by turning off Husky Stadium lights when the field is not in use. Birds and other animals living by the lake are negatively affected by excessive night lighting.

By stocking bird feeders and providing bird houses we can help build large populations of adapters and exploiters, which is a key feature in their ability to continually adapt and evolve in response to the challenges we present to them.

Finally, we live and work in such a wonderful and natural place that I hope we can all take a bit of time each day to celebrate the nature around us. Share that passion for life with colleagues, students and family members so that they, too, develop an ethic that, as Aldo Leopold wrote 60 years ago, values our land as a community, not simply a commodity.
