

# How low can you go? Take the Great Square challenge

December 10 2014, by Bob King

---

Look high in the southern sky at nightfall to find the familiar giant square that forms the barrel of Pegasus the Flying Horse. The map shows the sky around 6:30 p.m. local time. Credit: Stellarium

Cast your gaze up, up, up on the next dark, moonless night and stare into

the Great Square of Pegasus. How many stars do you see? Zero? Two? Twenty? If you'd like to find out how dark your sky is, read on.

The Great Square, one of the fall sky's best known star patterns, rides high in the south at nightfall in mid-December. It forms part of the larger figure of Pegasus the Winged Horse. For our purposes today, we're going to concentrate on what's inside the square.

Bounded by Alpheratz (officially belonging to adjacent Andromeda), Scheat, Markab and Algenib, the Great Square is about  $15^\circ$  on a side or one-and-a-half balled fists held at arm's length.

At first glance, the space appears empty, but a closer look from all but the most light polluted skies will reveal a pair 4th magnitude stars in the upper right quadrant of the square. Fourth magnitude is about the viewing limit from a bright suburban location.

Astronomers use the magnitude scale to measure star and planet brightness. Each magnitude is 2.5 times brighter than the one below it. Aldebaran, which shines at 1st magnitude, is 2.5 times brighter than a 2nd magnitude star, which in turn is 2.5 times brighter than a 3rd magnitude star and so on.

A first magnitude star is  $2.5 \times 2.5 \times 2.5 \times 2.5 \times 2.5$  (about 100) times brighter than a 6th magnitude star. The bigger the magnitude number, the fainter the star. From cities, you might see 3rd magnitude stars if you can block out stray lighting, but a dark country sky will deliver the Holy Grail naked eye limit of magnitude 6. Skywatchers with utterly dark conditions might glimpse stars as faint 7.5. My own personal best is 6.5.

Moonlight and especially light pollution reduce the number of stars we can see in the night sky. This specially prepared map shows slices of sky based on amateur astronomer and author John Bortle's Dark Sky Scale. Classes range from 1 (excellent with stars fainter than 7th magnitude visible) to 9 (inner city with a limiting magnitude of 4). Click for more detailed descriptions of each class and rate your own sky. Credit: International Dark Sky Association

With each drop in magnitude the number of stars you can see increases exponentially. There are only 22 first magnitude or brighter stars compared to 5,946 stars down to magnitude 6.

Ready to stretch your sight and rate your night sky? Step outside at nightfall and allow your eyes to dark-adapt for 20 minutes. With a copy of the map (above) in hand, start with the brightest stars and work your way to the faintest. Each every small step down the magnitude ladder prepares your eyes the next.

With a little effort you should be able to spot the four 4th magnitude range stars. At magnitude 5, you'll work harder. Moving beyond 5.5 can be very challenging. I revert to averted vision to corral these fainties. Instead of staring directly at the star, play your eye around it. Look a bit to this side and that. This allows a rod-rich part of the retina that's excellent at seeing faint stuff play through the scene and snatch up the faintest possible stars.

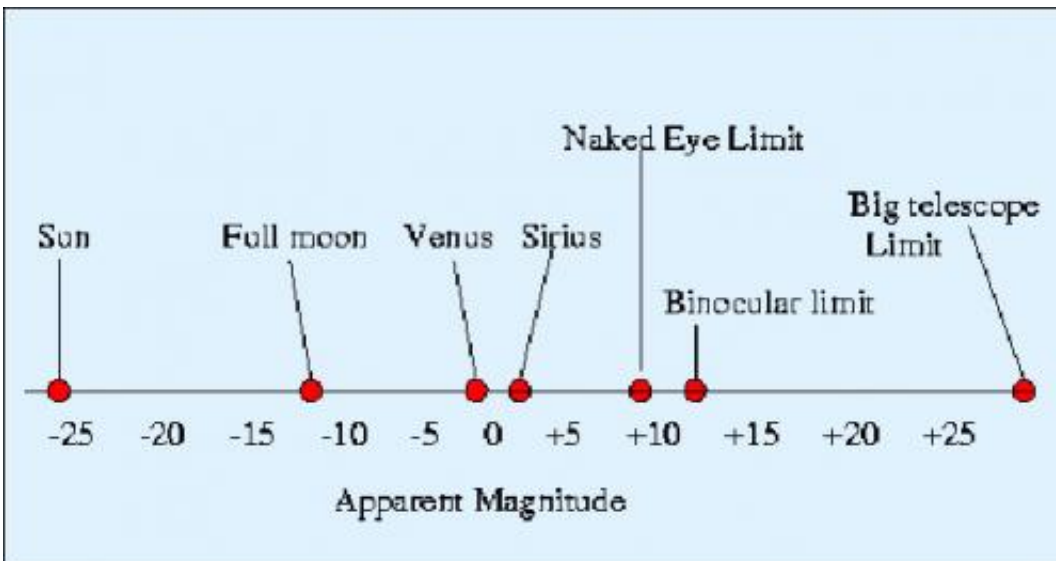

What appears blank at first is filled with stars — 26 of them down to magnitude 6.3 are visible inside the Great Square from a dark sky site. How many can you see? Click for a larger version. Credit: Stellarium

From my house I can pick out about dozen points of light inside the

Square on a moonless night. How many will you see? Once you know your magnitude limit, compare your result to John Bortle's Dark Sky Scale ... and weep. No, just kidding. But his Class 1 excellent sky includes a description of seeing [stars](#) down to [magnitude](#) 8 and the summer Milky Way casting shadows.

Hard to believe that before about 1790, when gas lighting was introduced in England, Class 1 skies were the norm across virtually the entire planet. Nowadays, most of us have to drive a hundred miles or more to experience true, untrammelled darkness.

Have fun with the challenge and let us know in the comments area how you do. Here's hoping you find the Great Square far from vacant.
