The extent to which galaxies consume one another has been revealed in research. Findings from the study help to explain how galaxies such as the Milky Way were formed.

A team of scientists has used a highly sensitive instrument on one of the world's largest telescopes to witness a dominant galaxy ingesting the stars of its near neighbours.

## Deep images

Astronomers took extremely wide-view, long exposures of a nearby group of [galaxies](#) known as the M81 Group, which lies 11.7 million light years from the Milky Way.

They observed the dominant central galaxy, M81, capturing stars from its two nearest neighbouring galaxies.

The gravitational pull of M81 was shown to distort the shapes of the other galaxies, pulling their stars into long tails, in a process called tidal stripping.

The images reveal for the first time how the stars from smaller galaxies are being ingested into M81.

It is expected that eventually the smaller galaxies will be devoured entirely.

## **Growing evidence**

The team, including researchers from the University of Edinburgh, were not surprised to see this process taking place.

However, the degree of interaction witnessed exceeded their expectations.

Findings from the study add to two decades of research during which evidence for this process has been mounting.

In the early 1990s, scientists discovered that our own Milky Way is in the process of subsuming a smaller system known as the Sagittarius dwarf galaxy.

The study, to be published in *Astrophysical Journal Letters*, was

conducted using the Hyper Suprime-Cam on the Subaru Telescope in Hawaii.

It was carried out by astronomers from Shanghai Astronomical Observatory, the National Astronomical Observatory of Japan, the Universities of Edinburgh and Cambridge, and Hiroshima University.

"The extremely faint outer regions of galaxies are challenging to study, but our findings reveal that they contain a wealth of information about how galaxies capture and cannibalise their smaller neighbours. This is important for understanding how large galaxies like our Milky Way have formed and evolved over time," Professor Annette Ferguson says.
