

National Guard airlifts dino fossils out of wilderness

October 29 2015, by Susan Montoya Bryan

Sgt. 1st Class Terrill Lee, from left, Sgt. James Ray and Staff Sgt. Noe Amador, secure the remains of a Pentaceratops, Thursday, Oct. 29, 2015, in the Bisti-De-Na-Zin Wilderness area south of Farmington, N.M. The fossils are encapsulated in heavy plaster jackets. They're being trucked to the New Mexico Museum of Natural History and Science in Albuquerque. (Jon Austria/The Daily Times via AP)

This was something that had never been seen before—the full skeletal

remains of a baby Pentaceratops, a plant-eating dinosaur with large horns that once roamed what is now North America tens of millions of years ago.

The fossils first caught the attention of paleontologists with the New Mexico Museum of Natural History and Science during a trek through the badlands of the Bisti Wilderness in northwestern New Mexico in 2011.

They knew they had to find a way to excavate and bring them back to the museum for further study.

After years of hard work and some paper pushing, a National Guard Blackhawk helicopter plucked the baby Pentaceratops' skull—encased in plaster—from the wilderness and airlifted it to a waiting cargo truck on Thursday morning. The team also airlifted the skull of an adult Pentaceratops that was found about 10 miles away.

The mission was mostly a success. Muddy conditions prevented the team from transporting a third and final plaster jacket that contained the remainder of the baby's skeleton. That will happen later.

Traditional means for excavating and removing the fossils were out the window because crews were working within wilderness, museum curator Spencer Lucas said. No vehicles or mechanized equipment are allowed.

They had to pack in hundreds of pounds of plaster, countless jugs of water and a battery of heavy tools for the job.

Less than 10 adult Pentaceratops skulls have been unearthed over the past century, and this marks the first baby skeleton and skull to ever be recovered, Lucas said.

With other dinosaurs, researchers have found the shape of the skulls can change dramatically from adolescence to adulthood.

"There's a lot of interesting questions," Lucas said. "We know what the

adult skull of a Pentaceratops looks like, but we've never seen a juvenile skull. So it will be interesting to see what the differences are in shape, the size of the horns and other kinds of features."

Pentaceratops, its head decorated with five horns, lived about 70 million years ago. Paleontologists suspect these rhinoceros-like dinosaurs may have used their horns for defense, but evidence also suggests that the horns and the shield-like part of the skull could have been used to attract mates. It's also thought they traveled in herds.

The remains of the young Pentaceratops appear to have been washed down through a streambed, as some of the skeleton has fallen apart. But how the animal met its demise is up for investigation, scientists said.

"Until we clean it up and really see how the bones are arranged and we look for things like tooth marks on the bone or something like that, we won't answer those questions. But these are things we're interested in," he said.

It could take many months for the museum to process the fossils. Officials are hopeful they can go on display at some point.

Curators are planning to open one of the plaster jackets containing the fossils next week. The public will be able to watch through windows that offer a view into the museum's laboratory.
