Computers have scanned aerial photographs and conducted the first automated mass-crowd count in the world, thanks to the work of

researchers at the University of Central Florida.

Counting large-scale crowds (such as the Million Man March in Washington, D.C.) has been a long, tedious process involving people examining [aerial photographs](#) one at a time. Until now, each photograph had to be divided into sections and the examiners counted the number of heads per inch.

But now, UCF's Center for Research in Computer Vision has created software that promises to automate the process and cut down the time dramatically, from up to a week to 30 minutes, giving organizers critical information when planning for events or responding to emergencies.

UCF's test run was conducted in September. Thousands of demonstrators along a 3.2-mile stretch of Barcelona were calling for the independence of the Catalonia province from Spain. Using the new software, 67 aerial images of different sections were analyzed.

The software program came up with a total count for each of the images within 30 minutes. The images and calculations were then sent to Pompeu Fabra University in Spain, where statistics professor Albert Satorra led a team in reviewing the data. Using UCF results for the images, they concluded the count for the entire crowd at about 530,000.

That number is well below the count claimed by rally organizers, said Haroon Idrees, a post-doctoral associate at the UCF center who conducted the analysis that was sent to Satorra.

"Automated computer analysis of such large-scale and dense crowds has never been done before," said Mubarak Shah, computer science professor and director of the center. "We will continue to push the envelope of state-of-the-art in-crowd analysis so that it can help the authorities and governments manage real-time safety of large crowds and

perform post-event analysis of such gatherings."

Crowd counts have been done digitally before, but not for large-scale crowds involving hundreds of thousands of people. The discipline is important because knowing the size of crowds can help organizers plan for events and can also help them have appropriate staffing available for emergencies.

"This is a huge milestone in how mass [crowds](#) are counted," said Dinesh Manocha, a computer science professor at the University of North Carolina at Chapel Hill not involved in the project. "UCF's computer-vision program has been the leading research group on developing computer-vision techniques for analysis of crowd videos and their research can have significant impact in terms of development of next-generation crowd-management technologies."
