

How Suomi NPP satellite orbits Earth and captures and transmits information home

April 12 2016, by Audrey Haar

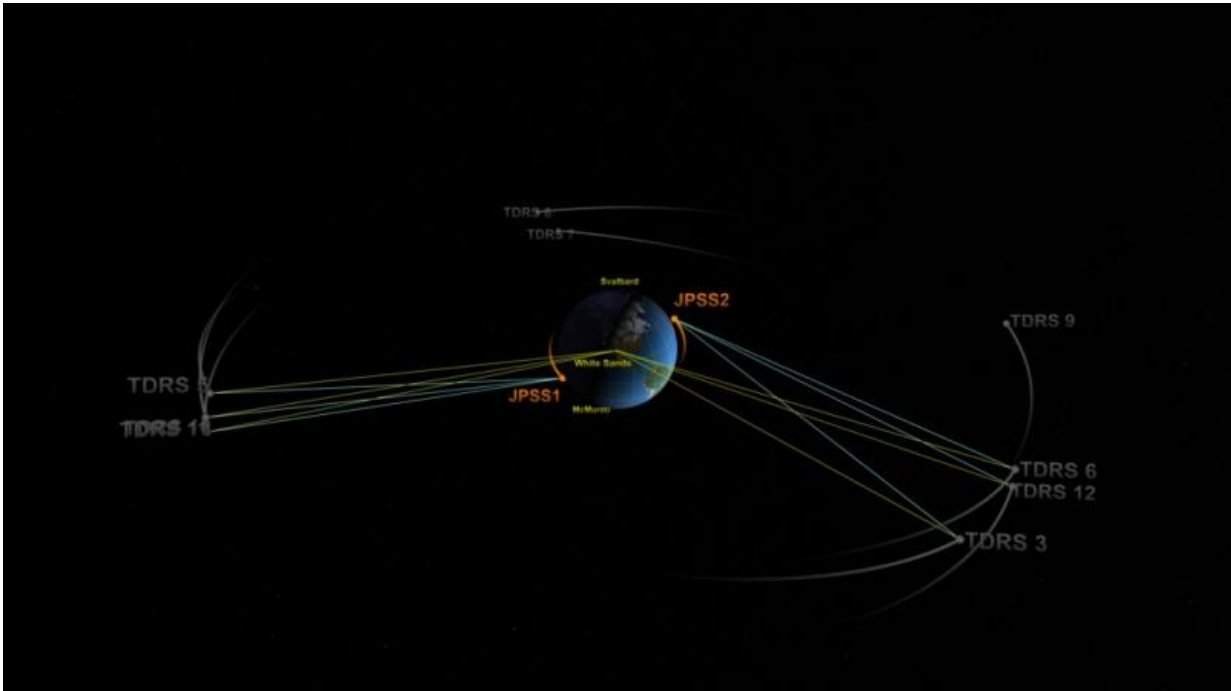

The JPSS-1 satellite will be inserted at a half-orbit separation from Suomi NPP.

These images illustrate how the Suomi National Polar-orbiting Partnership (Suomi NPP) satellite, a joint NASA/NOAA mission launched in 2011, circles Earth from pole-to-pole in a sun-synchronous orbit, with passes crossing the equator at the same local time.

It takes 14 orbits of the [satellite](#) to observe the entire Earth in one day, transmitting critical weather and climate data from its five instruments to Earth. This information enables weather forecasters and scientists to monitor and predict weather patterns with greater accuracy and to study long-term climate trends by extending the more than 30-year satellite data record.

These images also show how the next satellite in the series, NOAA's Joint Polar Satellite System-1 (JPSS-1) will be inserted into the same orbital plane as Suomi NPP, a half-orbit ahead of Suomi NPP, when it is launched in early 2017. This will enable JPSS-1 to orbit in tandem with Suomi NPP.

Suomi NPP's satellite information is currently transmitted to antennas at a [ground station](#) in Svalbard, Norway near the North Pole. With JPSS-1, there will also be a transmission to antennas at McMurdo Station, Antarctica near the South Pole. With JPSS-2, communication links will also be provided by satellites within NASA's Tracking and Data Relay Satellite (TDRS) network and the Svalbard, Norway ground [station](#). The TDRS network, orbiting 22,300 miles above Earth, provides critical communication support to NASA's human spaceflight endeavors and an array of science missions.

JPSS-1 and JPSS-2 satellites will use NASA's TDRS satellite network to relay data to the White Sands, New Mexico ground station in addition to the two JPSS polar ground stations in Norway and Antarctica. Credit: NASA/Goddard
