

# Turn down the volume: New IUCN guide helps navigate seismic survey impacts on marine species

September 2 2016

---

Whales and other cetaceans, pinnipeds, turtles, as well as fish and possibly other marine creatures, are all able to hear the intense sounds produced by seismic surveys. The effects of such operations on species can occur over very large areas in the ocean and include disruption of communication, stress and behavioral changes such as avoidance of key habitat. Credit: David Weller

A guide launched today by IUCN, International Union for Conservation of Nature, outlines best practices to ensure environmentally responsible seismic surveys and other forms of undersea mapping, with the aim of minimizing negative impacts of loud associated noise on marine life.

The guide was launched at the [IUCN World Conservation Congress](#) currently taking place in Hawai'i, USA.

Whales and other cetaceans, pinnipeds, turtles, as well as fish and possibly other marine creatures, are all able to hear the intense sounds produced by seismic surveys. The effects of such operations on species can occur over very large areas in the ocean and include disruption of communication, stress and behavioural changes such as avoidance of key habitat.

"The noise from seismic surveys can disrupt the essential life functions of marine species, such as breeding, nursing and foraging," says Carl Gustaf Lundin, Director of IUCN's Global Marine and Polar Programme. "It is therefore critical to turn down the volume and ensure the surveys are conducted in an environmentally responsible way. The new IUCN guide will help in achieving this."

The guide has been developed for governments, industry and scientists engaged in planning and conducting offshore seismic surveys and other forms of undersea mapping. It outlines best practices and tools for the entire process - from planning the survey and conducting the operation, to minimizing and monitoring the risk to vulnerable marine species, and evaluating potential impacts.

In seismic surveys, air guns towed behind ships repeat powerful bursts of sound. Sensors measure the return echo to reveal details of the sea floor and underlying geologic structure to a depth of several kilometres. Sound is a powerful tool for imaging and investigating the sea floor, and is

deployed mostly by the energy industry to pinpoint the location of oil or gas. Such surveys are also used for mapping the continental shelf, and for finding the best sites for new offshore wind energy projects.

The IUCN guide assesses the potential risk of various surveys on [marine life](#), and emphasises that surveys must take into account the specific circumstances related to the site. Key factors for consideration include the life history and population status of local species, environmental features and history, and nature of other operations in the area.

"Our guide is based on the best available science and methods," says one of the authors, Dr Douglas Nowacek of Duke University, who is a member of the Cetacean Specialist Group of IUCN's Species Survival Commission. "It draws on observations of operations and associated monitoring and mitigation efforts over several decades of geophysical and other industrial surveys."

"Undertaking a structured approach for planning and conducting environmentally responsible seismic surveys and other forms of seabed mapping is now more feasible than ever thanks to the lessons learned from previous operations, sustained research, and improvements in technology," says the other author, Dr Brandon Southall of Southall Environment Associates Inc. and University of California, Santa Cruz. "This guide will help managers and policymakers navigate this process."

Increased public awareness of the issue of human-generated noise in the ocean has been accompanied by greater involvement by governments and regulators. Parallel to IUCN's efforts, the US National Oceanic and Atmospheric Administration (NOAA), for example, is developing a national strategy for reducing underwater noise, a [draft](#) of which was released earlier in the year.

The world's governments, parties to the UN Convention on Biological

Diversity (CBD), are expected to adopt a number of measures recommended by scientists for addressing impacts of underwater noise on marine and coastal biodiversity at the next CBD meeting in Mexico in December 2016.
