

# Peru brain museum puts most complex organ on display

December 27 2016, by Luis Jaime Cisneros

---

Doctor Diana Rivas opens a jar containing a human brain immersed in formaldehyde at the Santo Toribio de Mogrovejo Hospital

It powers everything we do, yet remains one of our biggest mysteries.

But thanks to an unusual Peruvian museum dedicated entirely to the brain, visitors can get up close and personal with the most complex organ in the human body.

The "brain library" at the Santo Toribio de Mogrovejo Hospital in Lima has a massive collection of diseased and healthy brains, giving researchers and also the general public a glimpse of what is going on inside our heads.

It is the only museum in Latin America, and one of the few in the world, with a large collection of brains that is regularly open to the public.

The hospital, which was founded more than three centuries ago, has a total of 2,912 brains collected over the years, nearly 300 of which are on display in a mind-opening exhibit.

Some 20,000 people visit the museum each year.

"Touch a real skull," the museum invites them on arrival, proffering a specimen so visitors can feel the cranial bone structure and imagine how it holds two square meters (22 square feet) of intricately folded brain matter.

The brains of this operation, so to speak, is neuropathologist Diana Rivas, who is hovering over an icy steel table choosing scientifically interesting specimens to add to the museum's collection.

"This is where we do the autopsies. I handle them myself," she tells AFP, barely looking up from the brain she is holding in her gloved hands.

She has just removed this particular specimen from a jar of formaldehyde.

It is about the size of a deflated football, and "has the consistency of a rubber eraser," she says.

She examines the brain's two hemispheres, which resemble giant

walnuts, then carefully removes the thin layer of three membranes that hold them together, the meninges.

A collection of sick human brains is displayed at Santo Toribio de Mogrovejo Hospital

Once open, the organ's fascinating geography is on full display: a labyrinth of gray and white tissue that holds the mysteries of thought, language and virtually every bodily function inside.

## Food for thought

Rivas gives a lesson as she dissects.

"A [human brain](#) weighs between 1.2 and 2.4 kilos (2 pounds 10 ounces

and five pounds four ounces), depending on the height and weight of the person, and on the sex," she says.

"Women's are more evolved than men's. What differentiates us is the evolution of language, which we use much more than men."

The museum is divided into three parts: neuroanatomy, birth defects and [brain damage](#) caused by diseases such as cancer, Alzheimer's and the Zika virus.

"We show students what a healthy brain looks like, and then a sick brain, like this one with cysticercosis, which causes convulsions," she says, pointing to a brain stained with marks left by invading tapeworms.

The parasites are present in pork and can also be transmitted when people fail to wash their hands properly, she explains.

Offering more food for thought, she points to another sick brain affected by arteriosclerosis—the result of eating too much fatty food, which clogs the arteries, including the ones feeding the brain.

"This is to remind us not to get carried away with the hamburgers. It's not good to abuse fatty foods," she says, pointing out the brain's blackened blood vessels.

Speaking of food, she warns that visitors need a strong stomach for some parts of the exhibit, such as a display on encephalocele.

The fatal birth defect happens when the "neural tube" that becomes the brain and spinal cord fails to develop normally during pregnancy, leaving the [brain](#) and the membranes around it hanging out through an opening in the baby's skull.

"Around five percent of students are afraid when they see it. Some faint, others vomit," Rivas says matter-of-factly.
