

Sniffing out your dinner in the dark: How miniature predators get their favourite soil bacteria

December 8 2016

The bacteria in the soil excrete a specific smell, to communicate with each other. Researchers of the Netherlands Institute of Ecology (NIOO-KNAW) have now discovered that their predators also use the smell. Credit: iTZiT Visual Technology/NIOO-KNAW

Tiny predators in the soil can literally sniff out their prey: soil bacteria,

which communicate with each other using scent. A team of researchers from the Netherlands Institute of Ecology (NIOO-KNAW) has discovered that these predators - called protists - 'eavesdrop' on the bacteria's communication. It's a discovery that opens up perspectives for agriculture. The results are available online this month in *The ISME Journal*, from the publishers of *Nature*.

It's dark belowground, so having a good sense of smell is vital. NIOO's [soil](#) and microbial ecologists had already found out that soil [bacteria](#) tend to use scent to communicate with each other.

Lead author of the article Kristin Schulz-Bohm: "People, too, can smell some of these scents. Just think of the way the woods smell after a summer shower. It's produced by 'talking' bacteria. But it now turns out that the bacteria's [natural enemies](#) also take advantage of these scents."

'Long' distance

Protists are key predators of bacteria in the soil. Until now, it was unknown how protists sense their prey in such a complex and labyrinthine environment. Protists may be larger than bacteria, but they are still single-celled.

Scent, it now turns out, is especially important for long-distance communication - and of course if you're a micro-organism, most communication tends to be long distance. The [volatile organic compounds](#) (VOCs) responsible for these smells can 'carry' across distances of about ten centimetres.

Another thing the protists use smell for is to distinguish between different types of bacteria. It helps them choose the best or most attractive prey and go straight for that, believes soil ecologist and protist-expert Stefan Geisen, one of the members of the research team.

Unicellular protists are sniffing out their dinner: soil bacteria! Here we see *Saccamoeba lacustris*. Credit: Stefan Geisen/Netherlands Institute of Ecology (NIOO-KNAW)

Christmas trees

Terpenes are a key component of that 'aroma': the researchers found out that bacteria which could no longer produce terpenes, left the protists unaffected. Terpenes? "It's not a word many people would know", says Kristin Schulz-Bohm, "yet everyone knows what they are. Terpenes are what makes christmas trees smell like [christmas trees](#). Or think of mandarins, or lavender."

Possible practical applications for the team's discovery are already coming into view. "It may be possible to use these volatile organic compounds for biological pest control. To attract natural enemies of pathogens and other harmful micro-organisms." Terpenes: they're not

just for Christmas...
