A collaborative of researchers has developed a process to clean water containing heavy metals and organic pollutants using a new adsorbent material made from the peels of oranges and grapefruits.

The peels are a problem for the food industry, given that they take up a great volume and aren't very useful. An estimated 38.2 million tons of fruit peels are produced worldwide each year in the food [industry](#).

The researchers developed a new process by which it is possible to modify the structure of said residues via instant controlled pressure drop treatment, giving them adsorbent properties such as a greater porosity and surface area.

Researcher Luis Alberto Romero Cano explains that by using a subsequent chemical treatment, they have managed to add functional groups to the material, thus making it selective in order to remove metals and [organic pollutants](#) present in water.

A subsequent study carried out by the authors of this paper has showed that it is possible to pack those new materials in fixed bed columns, in a way similar to standard wastewater treatments. This laboratory-scale study has obtained parameters to design a large-scale use of the materials.

"The results show a great potential for the use of said [materials](#) as adsorbents capable of competing with commercial activated carbon for the adsorption and recovery of metals present in wastewater, in a way that could make it possible to carry out sustainable processes in which products with a great commercial value could be obtained from [food industry](#) residues," Romero Cano says.
