When food shopping, it's easy to overlook what it took to get your favorite meats and produce to the grocery store shelves. Anything perishable – beef, chicken, pork, vegetables, fruit, dairy and even water – must undergo a rigorous and time-consuming inspection process before shipping to its destination.

Angelo Gaitas, a research assistant professor in the Electrical and Computer Engineering Department, along with Gwangseong Kim, a

research scientist, are commercializing a [device](#) that reduces the screening process to just a few hours at the same cost as current devices.

If you've ever suffered from [food poisoning](#), you'll appreciate why it's so important to inspect [food](#) before it reaches the consumer. Food producers have to check for [bacteria](#) and signs of contamination before they are able to ship out any perishable food. Some common bacteria that can lead to foodborne illnesses include E.coli, salmonella and listeria. In fact, according to the Centers for Disease Control, each year, one in six Americans gets sick by consuming contaminated foods or beverages, that is 48 million people, out of whom 128,000 are hospitalized.

Typically, the inspection process, which involves putting samples in a solution and placing it in an incubator to see if bacteria grows, takes anywhere from 18 hours to several days. The reason is that it takes time for bacteria to grow at detectable levels. Current detection techniques are limited – you may need about 1,000 to a million bacteria present, depending on the technique, in a small volume before bacteria can be successfully detected. To reach that level, it takes time.

With this new device, [food producers](#) are able to run the whole solution through a smaller container inside the incubator oven. Antibodies in the device capture the target bacteria. This procedure allows bacteria to be concentrated in a smaller volume enabling same day detection.

"We are focused on helping food producers reduce storage cost and get fresher food to consumers," Gaitas says. "We are addressing a major and well documented need in a very large market. There are about 1.2 billion food tests conducted worldwide and about 220 million tests in the United States."

By shortening the detection time by one day, the team believes that the

device can save the food industry billions. For example, meat producers, as a collective industry, could save up to \$3 billion in storage costs by shortening the detection to one day. This device can also be used to expedite the detection of blood borne illnesses such as sepsis and viral infections; however, currently the commercial focus is on food due to the lower barriers to entry.
