

Hubble scopes out a galaxy of stellar birth

June 26 2017

Credit: ESA/Hubble & NASA

This image displays a galaxy known as ESO 486-21 (with several other background galaxies and foreground stars visible in the field as well). ESO 486-21 is a spiral galaxy—albeit with a somewhat irregular and ill-defined structure—located some 30 million light-years from Earth.

The NASA/ESA (European Space Agency) Hubble Space Telescope observed this object while performing a survey—the Legacy ExtraGalactic UV Survey (LEGUS)—of 50 nearby star-forming [galaxies](#)

. The LEGUS sample was selected to cover a diverse range of galactic morphologies, star formation rates, galaxy masses and more.

Astronomers use such data to understand how stars form and evolve within clusters, and how these processes affect both their home galaxy and the wider universe. ESO 486-21 is an ideal candidate for inclusion in such a survey because it is known to be in the process of forming new stars, which are created when large clouds of gas and dust (seen here in pink) within the galaxy crumple inwards upon themselves.
