

Australia has 2,000 missing persons and 500 unidentified human remains – a dedicated lab could find matches

January 31 2018, by Jodie Ward

It's been 52 years since the Beaumont children disappeared from Glenelg beach, Adelaide on Australia Day 1966.

In this case, excavation of a new area of interest – based on new evidence pointing to possible shallow graves – is <u>expected to commence</u> <u>this week</u>.

Sadly however, the Beaumont children are just three of around 2,000 long-term missing people in Australia. And we also have more than 500 sets of human remains believed to be archived across the country, that have not yet been identified.

It's time Australia committed to a laboratory solely dedicated to missing persons casework. Current capability in DNA forensics could allow us to match up remains with some of these missing persons cases, and potentially give families relief.

Forever wondering

New <u>research</u> shows 38,000 Australians are reported missing each year, around half of which are young people. Fortunately, most of those missing people are located alive within days of the report being made. However a small percentage of those reported missing have never been located.

But without clear evidence of life or death, it's very hard for families to know what's happened to their loved ones.

The <u>Beaumont children</u> is one of Australia's most enduring missing person cases. More recently, <u>William Tyrrell's disappearance</u> has had police tirelessly searching since 2014.

Last week the <u>Hayley Dodd missing persons case</u> was finally put to rest after 18 years, with Francis John Wark <u>found guilty of her murder</u>. However, until Hayley's remains are found and identified through DNA testing, her family won't have the answers they still long for.

DNA analysis was key in identifying the remains of <u>Daniel Morcombe</u> and <u>Matthew Leveson</u> in Australia.

Sources of DNA

Technology for <u>sequencing</u> DNA useful for genetic identification is now <u>cheaper, faster and better</u> than ever before.

A bone, tooth, nail, tissue or hair sample can commonly be used to obtain a DNA profile for a person. For recovered bodies, what is available and suitable will depend on the condition of the remains when they are found.

DNA testing may be the only way of positively identifying people in cases where:

It can be challenging to extract useable DNA from old, degraded bones. Credit: Jodie Ward, Author provided

• only a single bone was locatedbones from the one person have

been buried in multiple locationsbones are very old and degraded, or when the police have no other evidence or leads.

Of those 500 boxes of bones stored in mortuaries across Australia, the selection of an optimal bone fragment is likely to yield a DNA result in most cases. For those unidentified persons given a "destitute burial", hopefully a sample was taken and stored for DNA testing. For other, typically older cases of "John and Jane Does" – the names commonly given to unidentified people – some remains may need to be exhumed.

Once a sample from the remains has been tested, the DNA profile can be compared to a database of DNA profiles from missing persons. The missing person's toothbrush or hairbrush, or ideally a medical sample such as a newborn screening card, <u>could be used for this purpose</u>. Often these samples are not available, so <u>family members</u> of the missing can be used for DNA matching because they share similar and predictable patterns in their DNA profiles.

Global precendent

Using DNA matching to examine how many of Australia's 500 sets of unknown bones match with the 2,000 missing Australians would likely be successful for at least some cases.

DNA technology is being <u>recommended</u> and <u>used</u> globally to identify large numbers of missing persons from war, genocide, terrorist attacks or mass disasters. The <u>International Commission on Missing Persons</u> DNA-led program has identified more than 20,000 missing persons.

Also, a <u>new Australian DNA database capability</u> soon to be rolled out will <u>facilitate the sharing and comparing of DNA profiles</u> from unknown remains, missing persons and their relatives across state borders.

Let's solve some cases

We now need to focus on populating the new Australian database with DNA profiles from our stored bones and missing persons in order for identifications to be made. The establishment of a laboratory, solely dedicated to missing persons casework, would be the <u>best way forward</u> for such a large scale identification effort. The concentration of specialist expertise and technology under one roof would help bring families and loved ones closer to getting the answers they need.

This would be similar to the successful United States model, where the Missing Persons Unit at the <u>University of North Texas Center for</u> <u>Human Identification</u> processes the bulk of the missing persons casework across the country.

This approach also relies on suitable family members donating DNA reference samples for those missing persons that don't have a DNA profile already in the DNA database.

Forensic DNA phenotyping, which involves using DNA to predict the ancestry and physical appearance of an individual, should also be introduced as an intelligence tool for missing persons investigations. Applying this emerging technology to bones could <u>help narrow down</u> the list of possible missing persons, identify relatives that should be approached to donate a <u>DNA reference sample</u>, or add hair, eye and skin colour to <u>facial reconstructions of skulls</u>.

A <u>national DNA identification program</u> will be essential for identifying our unknown and missing citizens, and in the process solve some of Australia's most baffling cold cases.

DNA is the only viable solution left for identifying most of these individuals. But the DNA will continue to degrade the longer we wait, so

time is of the essence.

If remains are found at the suspected Beaumont children burial site, Australia's bone experts will have to apply specialist DNA technologies in an attempt to recover a profile suitable for identification.
