Skin squames (cells that peel off from the skin surface) are a source of food for the bacteria found in air-cooling units, which produce odours

even in a dust-free air-conditioning system, a study by Hong Kong Baptist University scholars revealed. This research is the first to show that the accumulation and bacterial degradation of skin squames in air-cooling units is positively correlated to the complaints of a urine-like smell in air-conditioned areas.

The study was led by Dr Lai Ka-man, Associate Professor of the Department of Biology of HKBU. It found that [skin](#) squames shed from the human body can contribute to ammonia and volatile fatty acid production by bacteria colonising air-cooling units. Skin squames consist of keratins, which are structural proteins that can be degraded by keratinase, enzymes produced by some bacteria.

The released protein-based fuel source is then consumed by bacteria and broken down to ammonium. With limited amounts of carbon available in the environment, it can lead to excessive amounts of ammonia emissions and lead to a urine-like smell. Other than keratins, skin squames also contain other microbial nutrients such as lipids and [fatty acids](#), and natural metabolites found on human skin. These nutrients are also consumed by the bacteria and are degraded into different kinds of volatile short-chain fatty acids often linked to the smell of body odours.

Dr Lai said air quality in indoor environments is associated with people's health and well-being and should be given due attention since many Hong Kong people spend more than 70 percent of their time indoors. She said [odour](#) leads to discomfort and low productivity, and it is commonly believed that odour problems are due to a dirty air-conditioning [system](#) containing accumulated dust and harbouring different types of microbes. Therefore, cleaning the system regularly is a general practice to eliminate the odour. However, the study found that odour was sometimes reported from clean air-conditioning systems without visible dust accumulation, and cleaning the system is not a sustainable measure to mitigate the odour emission.

Dr Lai also observed that although the Hong Kong Environmental Protection Department has issued the Indoor Air Quality (IAQ) guidelines, they are inadequate to help property inspectors and engineers to identify potential odour-causing units. Therefore, the team also investigated and compared 10 microbial samples from air-cooling units with and without odour complaints in order to improve the current IAQ inspection. After studying the biological properties of the isolated [bacteria](#), the team reported that Staphylococcus species emitted from the air-conditioning system may hint to a potential odour-causing unit.

Dr Lai said, "For effective long-term odour control, it is important to reduce the amount of skin squames from entering the air-cooling units. To do so, the simplest way is to install an appropriate filter to capture the skin squames in the air. The size of skin squames is generally larger than 10 micrometres (or 0.001 centimetres). A filter that can effectively capture particles less than this size should help improve the odour problem."
