

Making solar hydrogen generation more efficient in microgravity

July 16 2018, by Bob Yirka

Cross sectional illustration of a gas bubble evolution model on the thin-film and

nanostructured photoelectrode. Whereas H₂ is formed at discretionary nucleation spots on the thin-film electrode surface (a) resulting in gas bubble coalescence and the formation of a bubble froth layer, the nanostructured Rh surface favours the formation of H₂ gas bubbles at the induced Rh tips, catalytic hot spots (b). Here, concentration gradients along the surface facilitate H₂ transfer to the bubbles upon formation. The distance between the hot spots prevents the coalescence of the formed gas bubbles. An international team of researchers has found a way to make solar hydrogen generation more efficient in microgravity environments. In their paper published in the journal *Nature Communications*, the group describes what they learned from experiments with a photoelectrochemical cell falling in a drop tower.

In order to go very far in space, future astronauts will need some means for creating their own air and fuel—carrying enough of any of them for very long trips would prove impractical. Currently, astronauts aboard the ISS generate oxygen using a two-stage process. The first stage involves generating electricity using solar cells. In the second stage, the electricity is used to carry out an electrolysis technique with water. The researchers note that this process works, but it is inefficient. In this new effort, their goal was to improve the efficiency of the [electrolysis technique](#) used.

The researchers explain that the current process involves using an electrode made of a semiconductor that is light absorbing: Typically, a p-type indium phosphide. The electrode is then coated with a thin layer of a rhodium catalyst. As has been noted in the past, the inefficiency lies in the problem of [hydrogen bubbles](#) adhering to the surface of the electrodes, rather than bobbling up off them (due to buoyancy) as occurs on Earth. To get them to bobble up in a microgravity environment, the researchers changed the texture of the electrode. Rather than the normal

flat surface, the team forced the rhodium into peaks and valleys, with the distance between them too far for the [hydrogen](#) bubbles to sit in. That meant they had to sit on the peaks, which left less contact between the bubbles and the surface.

To test their idea, the researchers created capsules containing their apparatus and dropped them 120 meters down the Bremen Drop Tower in Germany. They note that each drop occurred over approximately 9.3 seconds—enough time for their device to produce [hydrogen gas](#).

The researchers found that their change to the [surface](#) of the [electrode](#) resulted in the production of hydrogen gas at the same rates as devices in normal gravity. They acknowledge that more work needs to be done, but suggest their approach looks promising.

Abstract

Long-term space missions require extra-terrestrial production of storable, renewable energy. Hydrogen is ascribed a crucial role for transportation, electrical power and oxygen generation. We demonstrate in a series of drop tower experiments that efficient direct hydrogen production can be realized photoelectrochemically in microgravity environment, providing an alternative route to existing life support technologies for space travel. The photoelectrochemical cell consists of an integrated catalyst-functionalized semiconductor system that generates hydrogen with current densities >15 mA/cm² in the absence of buoyancy. Conditions are described adverting the resulting formation of ion transport blocking froth layers on the photoelectrodes. The current limiting factors were overcome by controlling the micro- and nanotopography of the Rh electrocatalyst using shadow nanosphere

lithography. The behaviour of the applied system in terrestrial and microgravity environment is simulated using a kinetic transport model. Differences observed for varied catalyst topography are elucidated, enabling future photoelectrode designs for use in reduced gravity environments.
