

# Can China keep its climate promises?

March 26 2019, by Marlowe Hood

---

China can easily fulfill its Paris climate pledge to peak greenhouse gas emissions by 2030, but sourcing 20 percent of its energy needs from renewables and nuclear power by that date may be much harder

China can easily meet its Paris climate pledge to peak its greenhouse gas emissions by 2030, but sourcing 20 percent of its energy needs from renewables and nuclear power by that date may be considerably harder,

researchers said Tuesday.

Tripling the share of non-fossil fuels will require a major overhaul of China's recalcitrant power sector and the full deployment of a fledgling emissions trading system, they said in the journal *Nature Communications*.

There is a lot at stake.

If the world's top carbon polluter fails to achieve these and other voluntary targets, the 2015 treaty's cornerstone goal of capping global warming at "well below" two degrees Celsius (3.6 degrees Fahrenheit) may remain out of reach.

On current trajectories, the planet is set to warm twice that much by century's end.

China has also pledged to expand carbon-absorbing forests by 4,500 square kilometres before 2030, compared to 2005 levels.

"China is on track to achieve its climate commitments," lead author Kelly Sims, director of The Fletcher School's Climate Policy Lab at Tufts University, told AFP.

"It is not pulling back from implementing the Paris Agreement even though US President Donald Trump signalled his intention to do so."

Over the last decade, China has positioned itself as a global leader on climate action, enacting a raft of policies to slow the growth of its carbon footprint and, eventually, make it shrink.

Tripling the share of non-fossil fuels in China's energy mix will require a major overhaul of the country's recalcitrant power sector and the full deployment of a fledgling emissions trading system

Global warming, however, has not always been the main—or even the primary—target.

"The vast majority of China's policies have co-benefits for energy security, economic reform and reduced ground-level pollution," Sims told AFP.

More than a million—up to 2.8 million, according to a recent study—premature deaths in China each year are attributed to foul air.

## **Room for more ambition**

The only major climate policy exclusively aimed at reducing CO<sub>2</sub> levels is China's emissions trading scheme (ETS).

Introduced in 2017, it is set to cover more than 1,700 power companies and some three billion tonnes in greenhouse gas emissions.

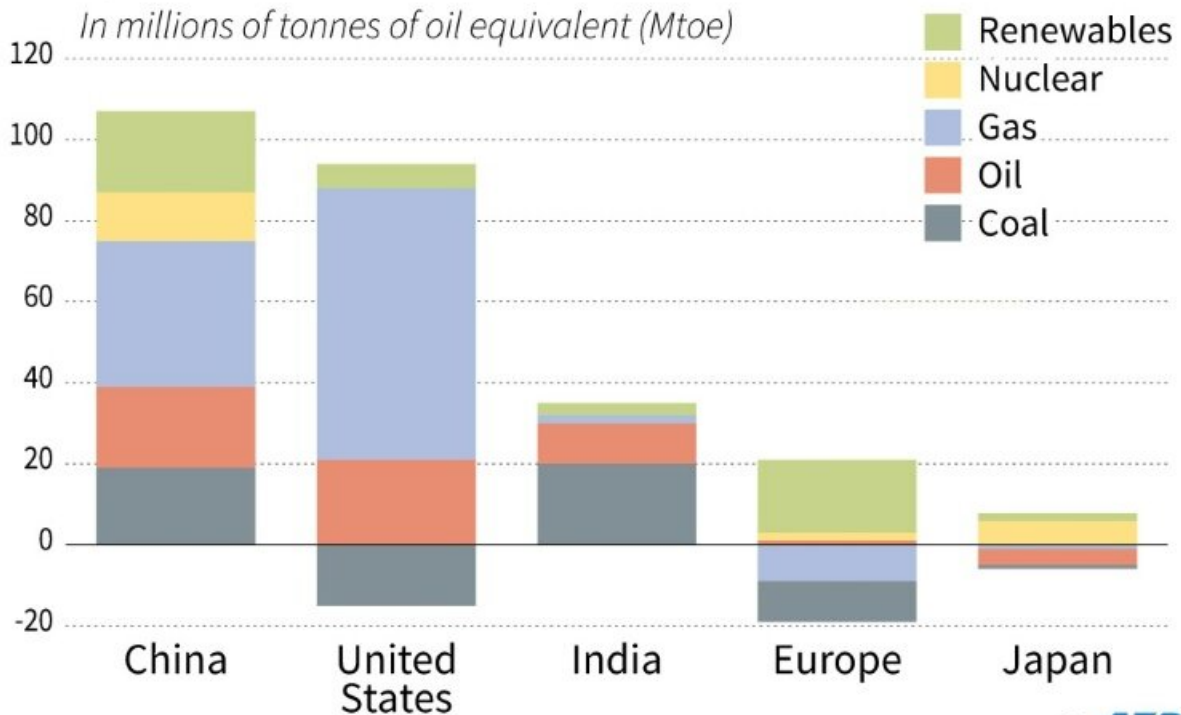

China's total emissions in 2018 topped 10 billion tonnes of CO<sub>2</sub>, well over a quarter of the world total.

Driving up the price of carbon within the ETS and boosting the share of renewables in China's electricity grid will both depend on revamping the country's power sector, the study said.

"The main challenge is completing power sector reform," said Sims.

Primary energy demand growth by fuel in major energy markets, change from 2017 to 2018

"There is political resistance from owners of existing coal plants, and from the provinces with major coal production and coal use."

To assess China's chances of meeting its carbon-cutting promises, Sims and colleagues canvassed 18 experts, and modelled the implementation of 14 climate policies.

China has come in for sharp criticism from watchdog groups for not

setting more ambitious carbon-cutting targets.

The Carbon Action Tracker, which evaluates the CO<sub>2</sub> reduction efforts in relation to capacity, has labelled Beijing's "highly insufficient."

"Discouragingly, a rise in coal consumption drove Chinese CO<sub>2</sub> emissions to a new high in 2017, which will likely be exceeded again in 2018," it noted.

But the experts said that Beijing still has plenty of time to put its emissions curve on a downward track before 2030.

"There is certainly room to be more ambitious in its peaking target," Sims added.

China is also under pressure to bring down—and account for—emissions of the potent greenhouse gas methane, a byproduct of both natural gas and livestock production.

"But China cannot stop climate change alone," Sims said.

"All of the major industrialised countries will need to reduce their emissions, and rapidly developing countries will need to implement alternative growth strategies with the help of wealthier countries."
