

Refugees from rising seas: no place to call home

September 22 2019, by Marlowe Hood and Amelie Bottollier-Depois

When rising seas displace hundreds of millions of people—a near certainty, scientists say—it will be an exodus with no hope of return

Most refugees fleeing persecution, famine or civil strife dream of one thing: going home some day.

But when rising seas displace hundreds of millions of people—a near certainty, scientists say—it will be an exodus with no hope of return.

"With sea level rise, we are talking about migrations without the option for a round-trip," Francois Gemenne, an expert on the intersection between geopolitics and the environment, and director of the Hugo Observatory in Liege, Belgium, told AFP.

The global ocean waterline has crept up 15 to 20 centimetres since 1900, a direct effect of climate change. Until recently, that added volume was mostly due to water expanding as it warms.

Today, however, meltwater from glaciers and especially ice sheets atop Greenland and Antarctica has become the main driver.

The pace of sea level rise has also picked up, increasing nearly three-fold in the last decade compared to the previous century, a landmark UN assessment of oceans and Earth's frozen spaces to be unveiled next week will report.

How high the oceans will be lifted by 2100 depends mainly on how much Earth heats up.

If humanity caps global warming at two degrees Celsius above preindustrial levels—the cornerstone goal of the Paris climate treaty—seas will rise by about half-a-metre, according to a draft of the Intergovernmental Panel on Climate Change (IPCC) report seen by AFP.

Rising sea levels

Even in the most optimistic scenario, rising sea levels could eventually displace 280 million people

Even if global warming is capped at 2C, oceans will eventually rise enough to submerging areas home to 280 million people today, according to the a draft IPCC report

A trickle to a torrent

A 3C or 4C world in which efforts to curb greenhouse emissions have fallen short will likely see an increase closer to a metre, enough to wreak havoc in dozens of coastal megacities and render many island nations uninhabitable.

"Some small islands in the Pacific and Indian Ocean are merely one to

two metres above sea level," Carlos Fuller, lead climate negotiator for the Association of Small Island States (AOSIS), told AFP.

"A 1.2 metre rise would totally submerge these states."

But even these dire impacts are a trickle compared to the torrent to come because ice sheets will continue to shed mass for hundreds of years, scientists warn.

In the 22nd century, the pace of sea-level rise is likely to jump 100-fold from 3.6 millimetres per year today to several centimetres annually, according to the draft IPCC report.

Even if <u>global warming</u> is capped at 2C, oceans will eventually rise enough to submerge areas home to 280 million people today, according to research led by Ben Strauss, CEO and chief scientist of Climate Central.

The potential for destruction—already evident today—comes mainly from tropical storm surge.

"Two degrees of warming translates into more than 4.5 metres of sea level rise, probably six," Strauss told AFP.

How high the oceans will be lifted by 2100 depends mainly on how much Earth heats up

"That's enough to erase most of the cities on the coastlines across the world today."

Local and national governments around the world are starting to come to grips with the reality of current and future sea level rise.

Engineered solutions

Some countries are getting ahead of the problem by moving <u>vulnerable</u> <u>populations</u>.

Indonesia announced last month that it will relocate its capital—along with millions of it residents—from Jakarta to Borneo.

Vietnam, meanwhile, is engineering an exodus from parts of the Mekong Delta to higher ground.

Local governments in Florida and Louisiana have created incentives to move people from flood-prone areas, and Britain has earmarked at least one vulnerable village in Wales to be "decommissioned".

"The message is that sea level rise is affecting the rich and the poor, developed and developing countries," said Fuller.

Some are taking an engineering approach. New York, for example, has a plan likely to cost tens of billions to protect parts of the city inundated in 2012 by Hurricane Sandy.
