Inspired by the unique and efficient swimming strategy of cephalopods, scientists developed an aquatic robot that mimics their form of propulsion.

These [high-speed](#), squidlike robots are made of [smart materials](#), which

make them hard to detect—an advantage that has potential military reconnaissance and scientific applications—while maintaining a low environmental footprint.

Physicists Xiaobo Bi and Qiang Zhu used [numerical simulations](#) to illustrate the physical mechanisms and fluid mechanics of a squid's swimming method, which uses intermittent bursts through pulsed jet propulsion. By using this form of locomotion, the new [device](#) can achieve impressive speeds, just like its animal inspiration. Bi and Zhu discuss their work in this week's *Physics of Fluids*.

When swimming, these squidlike machines suck water into a pressure chamber and then eject it. The soft-bodied device could be used as a platform for environmental monitoring by simultaneously using this feature to test water samples as it swims.

"In addition to the 2-D and 3-D numerical simulations presented in this article, we are working with an interdisciplinary team to build a prototype of the mechanical device, to perform both straight-line swimming and maneuvers," Zhu said. "This project will combine [fluid dynamics](#), control, smart materials and robotic design."

The device could be used as either a stand-alone swimmer or as a propeller of an underwater vehicle.

The researchers have not yet been able to maintain speeds that can last for more than a few cycles due to turbulence and instabilities, but they are working on ways to overcome this. Zhu hopes this research will provide a starting point for more sophisticated modeling and experimental studies to develop robots like their creation.
