

Archaeological discoveries are happening faster than ever before, helping refine the human story

December 24 2019, by Elizabeth Sawchuk and Mary Prendergast

Nearly a century ago, archaeologists started to shift the focus of human origins research from Europe to Africa's 'cradles of humankind' like Oldupai (Olduvai) Gorge in Tanzania. What will the next big shifts be? Credit: Manuel Domínguez-Rodrigo, [CC BY-SA](#)

In 1924, a three-year-old child's skull found in South Africa forever changed how people think about human origins.

The [Taung Child](#), our first encounter with an ancient group of proto-humans or [hominins](#) called [australopithecines](#), was a turning point in the study of human evolution. This discovery shifted the focus of human origins research from Europe and Asia onto Africa, setting the stage for the last century of research on the continent and into its "[Cradles of Humankind](#)."

Few people back then would've been able to predict what scientists know about evolution today, and now [the pace of discovery is faster than ever](#). Even since the turn of the 21st century, [human origins](#) textbooks have been rewritten over and over again. Just 20 years ago, no one could have imagined what scientists know two decades later about humanity's deep past, let alone how much knowledge could be extracted from a thimble of dirt, a scrape of dental plaque or satellites in space.

Human fossils are outgrowing the family tree

In Africa, there are now [several fossil candidates for the earliest hominin](#) dated to between 5 and 7 million years ago, when we know humans likely split off from other Great Apes based on differences in our DNA.

Although discovered in the 1990s, publication of the 4.4 million year old skeleton nicknamed "[Ardi](#)" in 2009 [changed scientists' views on how hominins began walking](#).

Rounding out our new relatives are a few australopithecines, including *Australopithecus deryiremeda* and [Australopithecus sediba](#), as well as a potentially late-surviving species of early *Homo* that reignited debate about when humans first began [burying their dead](#).

Perspectives on our own species have also changed. Archaeologists previously thought *Homo sapiens* [evolved in Africa around 200,000 years ago](#), but [the story has become more complicated](#). [Fossils](#)

[discovered in Morocco](#) have pushed that date back to 300,000 years ago, consistent with ancient DNA evidence. This [raises doubts that our species emerged in any single place](#).

Fossils like that of *Australopithecus sediba*, discovered in South Africa by a 9-year-old boy, are reshaping the human family tree. Credit: Prof Berger and Wits University, [CC BY-SA](#)

This century has also brought unexpected discoveries from Europe and Asia. From enigmatic "hobbits" on the Indonesian island of Flores to the Denisovans in Siberia, our ancestors may have encountered a variety of

other hominins when they spread out of Africa. Just this year, researchers reported a [new species from the Philippines](#).

Anthropologists are realizing that our Homo sapiens ancestors had [much more contact with other human species](#) than previously thought. Today, human evolution [looks less like Darwin's tree](#) and more like a [muddy, braided stream](#).

Ancient DNA reveals old relationships

Many recent discoveries have been made possible by the [new science of ancient DNA](#).

Since scientists fully sequenced the [first ancient human genome](#) in 2010, data from [thousands of individuals](#) have shed new insights on our species' origins and early history.

One shocking discovery is that [although our lineages split up to 800,000 years ago](#), modern humans and Neanderthals [mated a number of times](#) during the last Ice Age. This is why many people today possess some Neanderthal DNA.

Ancient DNA is how researchers first identified the [mysterious Denisovans](#), who interbred with us [and Neanderthals](#). And while most studies are still conducted on bones and teeth, it is now possible to extract ancient DNA from other sources like [cave dirt](#) and [6,000-year-old chewing gum](#).

Genetic methods are also reconstructing [individual](#) and [family relationships](#), and connecting ancient individuals to living peoples to end [decades-long debates](#).

The applications go far beyond humans. Paleogenomics is yielding

surprising discoveries about [plants](#) and [animals](#) from [ancient seeds and skeletons](#) hidden in the backrooms of museums.

The rise of biomolecular archaeology means new opportunities for interdisciplinary collaboration among field- and lab-based scientists. Credit: Christina Warinner, [CC BY-ND](#)

Biomolecules are making the invisible visible

DNA is not the only molecule revolutionizing studies of the past.

[Paleoproteomics](#), the study of [ancient proteins](#), can [determine the species of a fossil](#) and recently linked a [9-foot tall, 1,300-pound extinct ape](#) that lived nearly 2 million years ago to today's orangutans.

Dental calculus—the hardened plaque that your dentist scrapes off your teeth—is particularly informative, revealing everything from [who was drinking milk 6,000 years ago](#) to the surprising diversity of plants, some [likely medicinal](#), in Neanderthal diets. Calculus can help scientists understand [ancient diseases](#) and how the human [gut microbiome has changed over time](#). Researchers even find cultural clues—bright blue lapis lazuli trapped in a medieval nun's calculus led historians to reconsider who penned illuminated manuscripts.

Lipid residues trapped in pottery have revealed the [origins of milk consumption in the Sahara](#) and showed that oddly shaped pots found throughout Bronze and Iron Age Europe were ancient baby bottles.

Researchers use [collagen-based "barcodes"](#) of different animal species to answer questions ranging from when [Asian rats arrived as castaways on Africa-bound ships](#) to what [animals were used to produce medieval parchment](#) or even to detect [microbes left by a monk's kiss](#) on a page.

Big data is revealing big patterns

While biomolecules help researchers zoom into microscopic detail, other approaches let them zoom out. Archaeologists have used [aerial photography](#) since the 1930s, but widely available [satellite imagery](#) now enables researchers to [discover new sites](#) and [monitor existing ones at risk](#). Drones flying over sites help [investigate how and why they were made](#) and [combat looting](#).

The 2010 excavation in the East Gallery of Denisova Cave, where the ancient hominin species known as the Denisovans were discovered. Credit: Bence Viola. Dept. of Anthropology, University of Toronto, [CC BY-ND](#)

Originally developed for space applications, scientists now use LIDAR—a remote sensing technique that uses lasers to measure distance—to map 3-D surfaces and visualize landscapes here on Earth. As a result, ancient cities are emerging from dense vegetation in places like [Mexico](#), [Cambodia](#) and South Africa.

Technologies that can peer underground from the surface, such as Ground Penetrating Radar, are also revolutionizing the field—for example, [revealing previously unknown structures at Stonehenge](#). More and more, archaeologists are able to do their work without even digging a hole.

Teams of archaeologists are [combining big datasets](#) in new ways to understand large-scale processes. In 2019, over 250 archaeologists pooled their findings to show that humans have altered the planet for thousands of years, for example, with a [2,000-year-old irrigation system](#) in China. This echoes [other studies that challenge](#) the idea that the Anthropocene, the current period defined by human influences on the planet, [only began in the 20th century](#).

New connections are raising new possibilities

These advances bring researchers together in exciting new ways. Over [140 new Nazca Lines](#), ancient images carved into a Peruvian desert, were discovered using artificial intelligence to sift through drone and satellite imagery. With the wealth of high-resolution satellite imagery online, teams are also turning to [crowdsourcing](#) to find new archaeological sites.

Although new partnerships among archaeologists and scientific specialists are not always tension-free, there is growing consensus that studying the past means reaching across fields.

The [Open Science movement](#) aims to make this work accessible to all. [Scientists](#) including [archaeologists](#) are sharing data more freely within and beyond the academy. [Public archaeology](#) programs, community digs and digital museum collections are becoming common. You can even print your own copy of famous fossils from [freely available 3-D scans](#), or an [archaeological coloring book](#) in more than 30 languages.

Efforts to make [archaeology](#) and [museums](#) more equitable and engage [indigenous research partners](#) are gaining momentum as archaeologists consider [whose past is being revealed](#). Telling the human story requires a community of voices to do things right.

Scientists unexpectedly found lazurite pigment in calcified plaque clinging to a 11th- to 12th-century woman's tooth, challenging the assumption that male monks were the primary makers of medieval manuscripts. Credit: Christina Warinner, [CC BY-ND](#)

Studying the past to change our present

As new methods enable profound insight into humanity's shared history, a challenge is to ensure that these insights are relevant and beneficial in the present and future.

In a year marked by [youth-led climate strikes](#) and [heightened awareness of a planet in crisis](#), it may seem counterproductive to look back in time.

Yet in so doing, archaeologists are providing empirical support for climate change and revealing how ancient peoples coped with challenging environments.

As one example, studies show that while industrial meat production has [serious environmental costs](#), [transhumance](#)—a traditional practice of seasonally moving livestock, now [recognized by UNESCO as intangible cultural heritage](#)—is not only [light on the land](#) today, but helped promote [biodiversity and healthy landscapes](#) in the past.

Archaeologists today are contributing their methods, data and perspectives toward a vision for a less damaged, more just planet. While it's difficult to predict exactly what the next century holds in terms of archaeological discoveries, a new focus on "[usable pasts](#)" points in a positive direction.
