

Extreme conditions created a 'perfect storm' for catastrophic fires

A Western Sydney University Research Fellow has described the specific set of environmental conditions that led to Australia's bushfire emergency.

Dr. Rachael Nolan is a member of the Fire Research Group within the Hawkesbury Institute for the Environment at Western Sydney University.

Her research is focused on developing models of moisture levels in forests and bushlands—using a combination of weather data and satellite mapping technology.

Dr. Nolan says her analyses of bushlands around Sydney in the final months of 2019 indicated that the landscape was primed for these [catastrophic fires](#)—but it was series of other conditions, all happening concurrently, that ultimately led to the disaster.

"All of our data indicated that the 2019-20 bushfire season had the potential to be devastating," says Dr. Nolan.

"From September we were seeing suggestions that the forests were starting to suffer from the drought, and moisture levels were critically low. But we had been getting similar conditions for the last two seasons and our worst fears did not eventuate until now."

Dr. Nolan says there are four pre-conditions that are required for high-intensity wildfires of this magnitude:

1. The presence of a continuous fuel source, e.g. fallen leaves and twigs, shrubs;
2. That fuel being dry enough to burn;
3. The presence of an ignition source, e.g. a [lightning strike](#); and
4. Weather conditions that are favorable to fire spread, e.g. high temperatures, strong winds, and low humidity.

Dr. Nolan says the recent [drought conditions](#) were key to creating the "perfect storm" that allowed all four of these pre-conditions to occur

concurrently.

"Drought causes the moisture contained within leaves in eucalypt forests to decline, and can lead to canopy dieback and leaf shedding. Usually rainforests and gullies will be damp and act as a natural impediment to the spread of fire—but during extreme, [dry conditions](#), even these usually wet parts of the landscape can dry out and become available to burn, aiding the spread of fire across the landscape," says Dr. Nolan.

Following the drought conditions that primed the landscape for fire, Dr. Nolan says it was a combination of extreme weather conditions and the occurrence of ignitions that led this disaster to come to pass.

"If all preconditions are met an active fire can occur and spread quickly," says Dr. Nolan.

With multiple [large fires](#) still burning across NSW and in other states and the situation rapidly changing, Dr. Nolan says it is important to note that this record-breaking fire season is not yet over, with the south-eastern Australian fire season typically extending to the end of February.

"Only then, once fire severity mapping and post-[fire](#) field surveys are conducted, will we truly know the devastating impact of these fires."
