

Q&A: How climate change, other factors stoke Australia fires

January 3 2020, by Seth Borenstein

Australia's unprecedented wildfires are supercharged thanks to climate change, the type of trees catching fire and weather, experts say.

And these fires are so extreme that they are triggering their own thunderstorms.

Here are a few questions and answers about the science behind the Australian wildfires that so far have burned about 5 million hectares (12.35 million acres), killing at least 17 people and destroying more than 1,400 homes.

"They are basically just in a horrific convergence of events," said Stanford University environmental studies director Chris Field, who chaired an international scientific report on climate change and extreme events. He said this is one of the worst, if not the worst, climate change extreme events he's seen.

"There is something just intrinsically terrifying about these big wildfires. They go on for so long, the sense of hopelessness that they instill," Field said. "The wildfires are kind of the iconic representation of climate change impacts."

Q: IS CLIMATE CHANGE REALLY A FACTOR?

A: Scientists, both those who study fire and those who study climate, say there's no doubt man-made global warming has been a big part, but not the only part, of the fires.

In this Monday, Dec. 30, 2019, aerial photo, wildfires rage under plumes of smoke in Bairnsdale, Australia. Thousands of tourists fled Australia's wildfire-ravaged eastern coast Thursday ahead of worsening conditions as the military started to evacuate people trapped on the shore further south. Last year in Australia was the hottest and driest on record, with the average annual temperature 2.7 degrees Fahrenheit (1.5 degrees Celsius) above the 1960 to 1990 average, according to Australia's Bureau of Meteorology. Temperatures in Australia last month hit 121.8 F (49.9 C).

"What would have been a bad fire season was made worse by the

background drying/warming trend," Andrew Watkins, head of long-range forecasts at Australia's Bureau of Meteorology, said in an email.

Mike Flannigan, a fire scientist at the University of Alberta in Canada, said Australia's fires are "an example of climate change."

A 2019 Australian government brief report on wildfires and climate change said, "Human-caused climate change has resulted in more dangerous weather conditions for bushfires in recent decades for many regions of Australia."

Q: HOW DOES CLIMATE CHANGE MAKE THESE FIRES WORSE?

A: The drier the fuel—trees and plants—the easier it is for fires to start and the hotter and nastier they get, Flannigan said.

"It means more fuel is available to burn, which means higher intensity fires, which makes it more difficult—or impossible—to put out," Flannigan said.

In this satellite image released by Copernicus Sentinel imagery, 2020 twitter page dated Dec. 31, 2019, shows wildfires burning across Australia. (Copernicus Sentinel Imagery via AP)

The heat makes the fuel drier, so they combine for something called fire weather. And that determines "fuel moisture," which is crucial for fire spread. The lower the moisture, the more likely Australian fires start and spread from lightning and human-caused ignition, a 2016 study found.

There's been a 10% long-term drying trend in Australia's southeast and 15% long-term drying trend in the country's southwest, Watkins said. When added to a degree of warming and a generally southward shift of

weather systems, that means a generally drier landscape.

Australia's drought since late 2017 "has been at least the equal of our worst drought in 1902," Australia's Watkins said. "It has probably been driven by ocean temperature patterns in the Indian Ocean and the long term drying trend."

Q: HAS AUSTRALIA'S FIRE SEASON CHANGED?

A: Yes. It's about two to four months longer, starting earlier especially in the south and east, Watkins said.

"The fires over the last three months are unprecedented in their timing and severity, started earlier in spring and covered a wider area across many parts of Australia," said David Karoly, leader of climate change hub at Australia's National Environmental science Program. "The normal peak fire season is later in summer and we are yet to have that."

Q: IS WEATHER, NOT JUST LONG-TERM CLIMATE, A FACTOR?

FIEL - In this image made from video taken on Dec. 22, 2019, and provided by Oakbank Balhannah CFS, a koala drinks water from a bottle given by a firefighter in Cudlee Creek, South Australia. Thousands of koalas are feared to have died in a wildfire-ravaged area north of Sydney, further diminishing Australia's iconic marsupial, while the fire danger accelerated Saturday, Dec. 28, 2019 in the country's east as temperatures soared. (Oakbank Balhannah CFS via AP, File)

A: Yes. In September, Antarctica's sudden stratospheric warming—sort of the southern equivalent of the polar vortex—changed weather conditions so that Australia's normal weather systems are farther north than usual, Watkins said.

That means since mid-October there were persistent strong westerly

winds bringing hot dry air from the interior to the coast, making the fire weather even riskier for the coasts.

"With such a dry environment, many fires were started by dry lightning events (storms that brought lightning but limited rainfall)," Watkins said.

Q: ARE PEOPLE STARTING THESE FIRES? IS IT ARSON?

A: It's too early to tell the precise cause of ignition because the fires are so recent and officials are spending time fighting them, Flannigan said.

While people are a big factor in causing fires in Australia, it's usually accidental, from cars and trucks and power lines, Flannigan said. Usually discarded cigarettes don't trigger big fires, but when conditions are so dry, they can, he said.

Q: ARE THESE FIRES TRIGGERING THUNDERSTORMS?

In this image released Thursday, Jan. 2, 2020, from the Department of Environment, Land, Water and Planning in Gippsland, Australia, smoke rises from wildfires burning in East Gippsland, Victoria. Thousands of tourists are fleeing Australia's wildfire-ravaged eastern coast ahead of worsening conditions as the military started to evacuate people trapped on the shore further south. Cooler weather has aided firefighting and allowed people to replenish supplies. (DELWP Gippsland via AP)

A: Yes. It's an explosive storm called pyrocumulonimbus and it can inject particles as high as 10 miles into the air.

During a fire, heat and moisture from the plants are released, even when the fuel is relatively dry. Warm air is less dense than cold air so it rises, releasing the moisture and forming a cloud that lifts and ends up a thunderstorm started by fire. It happens from time to time in Australia and other parts of the world, including Canada, Flannigan said.

"These can be deadly, dangerous, erratic and unpredictable," he said.

Q: ARE THE AUSTRALIAN TREES PRONE TO BURNING?

A: Eucalyptus trees are especially flammable, "like gasoline on a tree," Flannigan said. Chemicals in them make them catch fire easier, spread to the tops of trees and get more intense. Eucalyptus trees were a big factor in 2017 fires in Portugal that killed 66 people, he said.

Q: HOW CAN YOU FIGHT THESE HUGE AUSTRALIA FIRES?

A: You don't. They're just going to burn in many places until they hit the beach, Flannigan said.

In this Monday, Dec. 30, 2019, aerial photo, acres of scorched land are seen in Bairnsdale, Australia. Thousands of tourists fled Australia's wildfire-ravaged eastern coast Thursday ahead of worsening conditions as the military started to evacuate people trapped on the shore further south. (Glen Morey via AP)

"This level of intensity, direct attack is useless," Flannigan said. "You just have to get out of the way... It really is spitting on a campfire. It's not doing any good."

Q: WHAT'S THE LONG-TERM FIRE FUTURE LOOK LIKE FOR AUSTRALIA?

A: "The extreme fire season in Australia in 2019 was predicted," said Australian National University climate scientist Nerilie Abram. "The question that we need to ask is how much worse are we willing to let this get? This is what global warming of just over 1 degree C looks like. Do we really want to see the impacts of 3 degrees or more are like, because that is the trajectory we are on."
