

Wildness in urban parks important for human well-being

As metropolises balloon with growth and sprawl widens the footprint of cities around the world, access to nature for people living in urban areas

is becoming harder to find.

If you're lucky, a pocket park might be installed next to a new condominium complex on your block, or perhaps a green roof tops the building where you work downtown. But it's unusual to find places in a city that are relatively wild—even though our evolutionary history suggests we need interactions with wild nature to thrive.

A new study led by the University of Washington has found that not all forms of nature are created equal when considering benefits to people's well-being. Experiencing wildness, specifically, is particularly important for physical and mental health, according to the study published Jan. 29 in the journal *Frontiers in Sustainable Cities*.

Past research has found health and wellness benefits of nature for humans, but this is the first study to show that wildness in [urban areas](#) is profoundly important for human well-being.

"It was clear from our results that different kinds of nature can have different effects on people," said lead author Elizabeth Lev, a graduate student in the UW School of Environmental and Forest Sciences. "The wilder areas in an urban park seem to be affording more benefits to people—and their most meaningful interactions depended on those relatively wild features."

While these findings likely hold true in most [major cities](#), the research team focused on Discovery Park in Seattle, the city's most expansive urban park, which encompasses about 500 acres. The park, less than a 20-minute drive from the downtown core, has faced development pressures common for parks in cities with burgeoning populations.

The park's advisory board asked the UW researchers to look at what elements were most important to people who visit, with the goal of gaining usable information for decision-makers.

"We looked at Discovery Park, but this is about the entire planet," said

senior author Peter Kahn, a UW professor of environmental and forest sciences and psychology. "Everywhere, development is chipping away at wild areas. Humanity has caused so much destruction and there's no stopping it—unless we stop. We're trying to show that if you're going to develop an area, you at least need to understand the human costs."

The research team surveyed several hundred park-goers, asking them to submit a written summary online of a meaningful interaction they had with nature in Discovery Park. The researchers then pored over these submissions, coding experiences into different categories. For example, one participant's experience of "We sat and listened to the waves at the beach for a while" was assigned the categories "sitting at beach" and "listening to waves."

Across the 320 participant submissions, a pattern of categories the researchers call a "nature language" began to emerge. After coding all of the submissions, half a dozen categories—what the researchers call "interaction patterns"—were noted most often as important to visitors. These include encountering wildlife, walking along the edge of water, gazing out at a view and following an established trail.

Additionally, the researchers looked at whether the park's relative wildness was important in each visitor's most meaningful experiences in the park. They defined "relatively wild" as including Discovery Park's varied and relatively unmanaged land, its high levels of biodiversity, its "big nature" like old growth trees, large open spaces, expansive vistas, and people's experience of the park's solitude and removal from civilization.

These wild features were important to people's experiences, in nearly every case. For example, "spotting bald eagle" references a relatively

wild bird, and "watching birds perched on an old growth tree," denotes a wild habitat where that tree can thrive.

Naming each nature experience creates a usable language, which is important for people to be able to recognize and take part in the activities that are most fulfilling and meaningful to them. For example, the experience of walking along the edge of water might be fulfilling for a young professional on a weekend hike in the [park](#). Back downtown during a workday, they can enjoy a more domestic form of this interaction by walking along a fountain or water feature on their lunch break.

"We're losing the language of interaction with nature and as we do, we also lose the cultural practice of these deep forms of interaction with nature, the wellsprings of human existence," Kahn said. "We're trying to generate a nature language that helps bring these human-nature interactions back into our daily lives. And for that to happen, we also need to protect nature so that we can interact with it."

The researchers hope this study—and future ones conducted in other cities—can be used as part of the decision-making process for development proposals in parks and urban [natural](#) areas. They compiled their analysis methods into a handbook that can be used to undertake similar studies in other cities around the world.
