

Small protein that synchronizes the circadian clocks in shoots and roots

April 13 2020

Five years ago, researchers from the Centre for Research in Agricultural

Genomics (CRAG) led by the CSIC Research Professor Paloma Mas made the breakthrough discovery that the circadian clocks in the growing tip of the plant shoot function in a similar way to the clocks in the mammalian brain, which in both cases are able to synchronize the daily rhythms of the cells in distal organs. From that seminal finding, plant researchers have been eager to discover the messenger molecule that could travel from the shoot to the root to orchestrate the rhythms. The answer has been published in *Nature Plants* by Paloma Mas' team and collaborators from Japan, the U.K., and the U.S. They have identified a small essential clock protein called ELF4 as the required messenger. Furthermore, through a series of ingenious experiments, the researchers discovered that the movement of this molecule is sensitive to the ambient temperature.

The circadian clock is guided by the activity of proteins

Most living organisms, including humans and [plants](#), have an internal biological clock that allows them to anticipate and adapt to the [environmental changes](#) produced by the 24 hour Earth cycle. In plants, this circadian biological clock is crucial to set up the time for germination, growth and flowering, among other processes. The circadian clock is built of a set of cellular proteins whose amount and activity oscillate daily. The researchers who discovered this mechanism were awarded with the Nobel Prize in Physiology or Medicine in 2017.

Every plant cell contains a circadian clock, that is, all the machinery needed to adapt its responses to the 24-hour cycle. Nevertheless, as CRAG researchers published in a seminal article in *Cell* (2015), plants, as mammals, have a master circadian clock, which synchronizes peripheral clocks dispersed throughout the plant. The CSIC professor Paloma Mas explains: "we knew that there was a circadian signal that

moves from shoots to roots, but we did not know about the nature of this signal. It could have been hormones, photosynthetic products... Now, we have discovered that it is a core [protein](#) of the circadian clock that moves through the plant vasculature."

The researchers designed grafting experiments with the model plant *Arabidopsis thaliana*, connecting different shoots into several roots in which the clock was not working properly. These experiments allowed them to identify the clock protein ELF4, an acronym that accounts for "EARLY FLOWERING 4" as the messenger that moves from shoots to roots to convey circadian information.

ELF4 delivers temperature information to the roots

Anyone who has ever experienced jet lag, knows that the circadian biological clock is able to reset itself by environmental light cues, allowing the body to adapt to the new time zone within few days. In the same way that the circadian clock can synchronize to environmental light, it can also integrate information about [ambient temperature](#).

To discern if the ELF4 protein was transmitting to the roots information about light or temperature changes, the two main regulators of the [circadian clock](#), the researchers tested ELF4 movement under different environmental conditions. They discovered that at lower temperatures (12C), ELF4 mobility from shoots to roots was favoured, resulting in a slow-paced root clock. Instead, when the experiments were performed at higher temperatures (28C), they observed less ELF4 movement, which lead to a faster root clock. This newly described mechanism could provide an advantage for optimal root responsiveness to [temperature](#) variations.

Knowledge to live in a climate changing world

The research could have an impact in the near future. "Climate change and the associated higher temperatures are causing drought, which is already affecting crop productivity in agriculture. Knowing the genes and proteins that plants use to adapt their physiology to the environmental conditions will allow us to design better adapted crops, which will be key to ensure [food security](#)," explains CRAG researcher Paloma Mas.
