

Elucidation of nanostructures in practical heterogeneous catalysts

May 27 2020

The nanostructure of the heterogeneous Ziegler-Natta catalyst was clarified on the basis of cutting-edge analytical techniques. Left: Typical synchrotron data and the determined nanoparticle model of the catalyst primary particle. Right: Experimental Far-IR spectra of a series of catalyst supports, and Wulff's polyhedra derived on the basis of surface formation energy. Scientists from Japan Advanced Institute of Science and Technology

(JAIST) and University of Torino (UNITO) have cooperatively clarified the nanostructure of the heterogeneous Ziegler-Natta catalyst by means of combined synchrotron X-ray analytical techniques, vibrational spectroscopies, and molecular simulations.

Understanding the structure and the working principle of practical catalysts is largely beneficial for designing catalysts with desired functions. However, this is often infeasible due to the inherent complexity of such catalysts. The Ziegler-Natta [catalyst](#) is one of the most sophisticated practical catalysts for its performance in producing desired polyolefins at extremely high yield. Nonetheless, the structure of the nanosized building unit of this catalyst has not been fully understood over six decades.

The collaborative research teams of Japan and Italy quantitatively determined the structural disorder and the dimensions of the building unit based on [synchrotron](#) X-ray total scattering analysis aided with molecular simulations. Further, by combining infrared spectroscopies with state-of-the-art DFT simulations, the morphology and the surface exposure of the [building](#) unit were clarified. The current research corresponds to the first attempt of adopting synchrotron X-ray total scattering and Far IR spectroscopy for the study of the Ziegler-Natta catalyst. Such the multi-faced approach successfully shed new light on the full elucidation of the nanostructure in practical heterogeneous catalysts.

Papers titled "Revisiting the identity of δ -MgCl₂: Part I. Structural disorder studied by synchrotron X-ray total scattering" and "Revisiting the identity of δ -MgCl₂: Part II. Morphology and exposed surfaces studied by vibrational spectroscopies and DFT calculation" are both published in the *Journal of Catalysis*.
