With the increasing demand for affordable and sustainable energy, the ongoing development of batteries with a high energy density is vital. Lithium-sulfur batteries have attracted the attention of academic researchers and industry professionals alike due to their high energy density, low cost, abundance, nontoxicity and sustainability. However, Li-sulfur batteries tend to have poor cycle life and low energy density due to the low conductivity of sulfur and dissolution of lithium polysulfide intermediates in the electrolytes, which are generated when pure sulfur reacts with Li-ions and electrons.

To circumvent these challenges, a multi-institutional research team led by Chunsheng Wang at the University of Maryland has developed a new

chemistry for a sulfur cathode, which offers increased stability and higher energy of Li-sulfur batteries. Chao Luo—an assistant professor of chemistry and biochemistry at George Mason University—served as first author on the study, published in the *Proceedings of the National Academy of Sciences (PNAS)* on June 15.

Numerous conductive materials such as graphene, [carbon nanotube](#), porous carbon and expanded graphite were used to prevent the dissolution of polysulfides and increase the electrical conductivity of sulfur cathodes—the challenge here is encapsulating the nano-scale sulfur in a conductive carbon matrix with a high sulfur content to avoid the formation of polysulfides.

"We used the chemical bonding between sulfur and oxygen/carbon to stabilize the sulfur," Luo said. "This included a high temperature treatment to vaporize the 'pristine' sulfur and carbonize the oxygen-rich organic compound in a vacuum glass tube to form a dense oxygen-stabilized sulfur/carbon composite with a high sulfur content."

In addition, scanning [electron microscope](#) (SEM) and [transmission electron microscopy](#) (TEM) instruments, X-ray photoelectron spectroscopy (XPS) and pair distribution function were used to illustrate the reaction mechanism of the electrodes.

"In the dense S/C composite materials, the stabilized sulfur is uniformly distributed in carbon at the molecular level with a 60% sulfur content," Wang said. "The formation of solid electrolyte interphase during the activation cycles completely seal the sulfur in a carbon matrix, offering superior electrochemical performance under lean electrolyte conditions."

Li-sulfur batteries have applications in household and handheld electronics, electric vehicles, large scale energy storage devices and beyond.
