Long-term research is important to understand how land management impacts runoff and erosion, which pose serious threats to soil and water quality worldwide. To better understand these processes in agricultural landscapes of the southern Great Plains of the United States, eight 1.6-ha watersheds were established and instrumented in 1976 at the USDA-

ARS Grazinglands Research Laboratory in El Reno, Oklahoma.

Researchers recently summarized 23 years of data from the site in the *Journal of Environmental Quality*, showing the effects of native tallgrass prairie and crop-livestock systems on erosion and [water quality](#) (nitrogen, phosphorus, and suspended sediments).

The watersheds were equipped to measure precipitation and surface runoff quantity and quality. Initially, all watersheds were in native tallgrass prairie, but later four of the them were cropped into [winter wheat](#) (two conventionally tilled, one no-till, and one no-till with a summer forage crop), while the other four watersheds remained in native tallgrass prairie.

The authors described available archived [historical data](#), including methods of collection and analyses. Such a long-term research database is essential for determining the impact of different agricultural management systems, understanding the processes related to hydrologic transport and water quality, and validation and development of models capable of defining hydrology responses and water quality.
