

Identification of new 'oxidative stress sensor' MTK1

July 28 2020

Oxidative stress-induced MTK1 activation requires both oxidation and reduction of MTK1. Cells were treated with H₂O₂ for the indicated times. Cell extracts were electrophoresed under non-reducing conditions and immunoblotted with an anti-Myc antibody (top). Immunoprecipitated Myc-MTK1 was electrophoresed under reducing conditions and probed with anti-P-MTK1 or anti-Myc antibodies (middle and bottom). In an aging society, various studies are being conducted to explore the relationship between active oxygen and aging-related diseases such as cancer, chronic inflammatory diseases, and metabolic syndrome.

A research group at the Institute of Medical Science, The University of Tokyo in Japan, led by Professor Mitsuhiro Takekawa, has uncovered a new [mechanism](#) that elicits a cellular response by detecting [oxidative stress](#) in the [human body](#). MTK1 SAPKKK is identified as a new human oxidative stress sensor that senses excess active oxygen in the body and transmits that information to cells, leading to [cell death](#) and inflammatory cytokine production. The results of this research were published in *Science Advances* on June 24, 2020.

MTK1 SAPKKK perceives the cellular redox state and transduces it into SAPK signaling

Living organisms obtain the energy necessary for life activities by oxygen respiration. However, it is known that reactive oxygen species are generated in the human body as a by-product in the process.

Overproduction of active oxygen causes damage to cells and causes various diseases such as aging, cancer, chronic inflammatory diseases (rheumatoid arthritis, etc.), metabolic syndrome, and neurodegenerative diseases. Therefore, it is thought that the human body is equipped with a mechanism for sensing and appropriately responding to the oxidative stress state caused by overproduction of active oxygen. However, the detailed mechanism was unknown.

Both the MTK1 and ASK1 SAPKKKs are major mediators of oxidative stress-induced SAPK signaling. However, they have different time and dose response characteristics. While ASK1 rapidly and sensitively responds to oxidative stress, and induces early and transient activation of SAPKs, MTK1 is relatively less sensitive to oxidative stress and slowly activated. However, once MTK1 is activated, it can elicit prolonged SAPK activation to dictate cell fate decisions. GARD, GADD45-binding and redox-sensor domain. Credit: ©TAKEKAWA Mutsuhiro

Cells respond to oxidative stress by inducing intracellular signaling,

including the stress-activated p38 and JNK MAPK (SAPK) pathways, but the underlying mechanisms remain unclear. The research team reports that MTK1 SAPKKK functions as an oxidative stress sensor that perceives the cellular redox state and transduces it into SAPK signaling.

Following oxidative stress, MTK1 is rapidly oxidized and subsequently gradually reduced at evolutionarily conserved cysteine residues. These coupled oxidation-reduction modifications of MTK1 elicit its catalytic activity.

Gene knockout experiments showed that oxidative stress-induced SAPK signaling is mediated by coordinated activation of the two SAPKKKs, MTK1 and ASK1, which have different time and dose response characteristics.

They found that the MTK1-mediated redox sensing system is crucial for delayed and sustained SAPK activity and dictates cell fate decisions including cell death, and IL-6 production during respiratory burst in macrophages. Their results delineate a molecular mechanism by which [cells](#) generate optimal biological responses under fluctuating redox environments.

For details of the research, please see the paper.

THP-1 cells were infected with retroviruses expressing two different shRNAs against MTK1 (#1 or #2). Infected cells were drug-selected, pooled and assayed for MTK1 expression by immunoblotting (left). The indicated MFs were stimulated with zymosan for the indicated times. The expression level of IL-6 mRNA was analyzed using qRT-PCR (right). Credit: ©TAKEKAWA Mutsuhiro

Application to the treatment of cancer, metabolic syndrome

Professor Takekawa, at the Institute of Medical Science, the University of Tokyo, says, "This study has revealed a part of the oxidative stress response mechanism of the human body. The Cys residue in the MTK1 molecule, which is important for its function as an oxidative stress sensor, is highly conserved not only in humans but also in a wide variety of vertebrates, and the MTK1-mediated oxidative [stress](#) response is also evolutionarily conserved. This is strongly suggestive that the mechanism is common to various vertebrates."

The research group hopes that the findings of this research will be used in the future to develop therapeutic agents for various diseases related to reactive [oxygen](#) species such as cancer, chronic inflammatory diseases, and metabolic syndrome. These results were obtained as a cooperative effort with Professor Hiroaki Miki at Research Institute for Microbial Diseases, Osaka University in Japan.
