Infrared nonlinear optical (IR–NLO) materials are crucial for a broad range of applications, such as signal communication, microscopy and data processing. Yet, the challenge is how to obtain a strictly structural

non-centrosymmetric (NCS) compound, which is the primary requirement for the IR–NLO materials.

In a study published in *Chemistry of Materials*, the research team led by Prof. Zhu Qilong and Prof. Lin Hua from Fujian Institute of Research on the Structure of Matter (FJIRSM) of the Chinese Academy of Sciences proposed a partial isovalent anion substitution (PIAS) strategy to design and synthesize a novel IR–NLO material SrGeOSe<sub>2</sub>.

The researchers have, for the first time, reported the structural transformation from centrosymmetric (CS) compound SrGeO<sub>3</sub> to NCS SrGeOSe<sub>2</sub> through a generic and effective PIAS strategy.

They found that SrGeOSe<sub>2</sub> exhibits the desired balance between a strong powder second harmonic generation efficiency (SHG = 1.3 × benchmark AgGaS<sub>2</sub>) and a large laser-induced-damage threshold (LIDT = 36 × benchmark AgGaS<sub>2</sub>).

Theoretical calculations indicated that the large second-harmonic generation (SHG) efficiency mainly originates from the cooperative effects of 1-D heteroligand [GeO<sub>2</sub>Se<sub>2</sub>] asymmetric building units.

This study provides a powerful way to rationally induce the symmetry breaking and enhance the local dipole moments of the active units.
