

Canada's last intact ice shelf collapses due to warming

August 8 2020, by Seth Borenstein

This July 2015 photo taken by University of Ottawa glaciology professor Luke Copland shows Canadian Ice Service ice analyst Adrienne White taking a photo of cracks of the Milne Ice Shelf, which just broke apart. The Milne ice shelf was one of the Arctic's few remaining intact ice shelves, but at the end of July 2020 about 43% broke off. Scientists say that without a doubt it's man-made global warming. Much of Canada's remaining intact ice shelf has broken apart into hulking iceberg islands thanks to a hot summer and global warming, scientists said.

Canada's 4,000-year-old Milne Ice Shelf on the northwestern edge of Ellesmere Island had been the country's last intact ice shelf until the end of July when ice analyst Adrienne White of the Canadian Ice Service noticed that satellite photos showed that about 43% of it had broken off. She said it happened around July 30 or 31.

Two giant icebergs formed along with lots of smaller ones, and they have already started drifting away, White said. The biggest is nearly the size of Manhattan—21 square miles (55 square kilometers) and 7 miles long (11.5 kilometers). They are 230 to 260 feet (70 to 80 meters) thick.

"This is a huge, huge block of ice," White said. "If one of these is moving toward an oil rig, there's nothing you can really do aside from move your oil rig."

The 72-square mile (187 [square kilometer](#)) undulating white ice shelf of ridges and troughs dotted with blue meltwater had been larger than the District of Columbia but now is down to 41 square miles (106 [square kilometers](#)).

Temperatures from May to early August in the region have been 9 degrees (5 degrees Celsius) warmer than the 1980 to 2010 average, University of Ottawa glaciology professor Luke Copland said. This is on top of an Arctic that already had been [warming](#) much faster than the rest of globe, with this region warming even faster.

"Without a doubt, it's [climate change](#)," Copland said, noting the ice shelf

is melting from both hotter air above and warmer water below. "The Milne was very special," he added. "It's an amazingly pretty location."

Ice shelves are hundreds to thousands of years old, thicker than long-term sea ice, but not as big and old as glaciers, Copland said.

Canada used to have a large continuous ice shelf across the northern coast of Ellesmere Island in the Canadian territory of Nunavut, but it has been breaking apart over the last decades because of man-made [global warming](#), White said. By 2005 it was down to six remaining ice shelves but "the Milne was really the last complete [ice shelf](#)," she said.

"There aren't very many ice shelves around the Arctic anymore," Copland said. "It seems we've lost pretty much all of them from northern Greenland and the Russian Arctic. There may be a few in a few protected fjords."
