A small number of social media users could be responsible for amplifying and boosting a disproportionate amount of COVID-19

disinformation, a report says.

Academics at Cardiff University's Crime and Security Research Institute investigated people's activities on social [media](#) in five countries—the UK, France, Germany, Italy and Spain—via a survey conducted between 18 March and 30 April.

The team has identified a group they label as "super-sharers", who amount to 6% of social media users and were much more likely to have shared COVID-19 disinformation. These individuals possess a number of common traits: They have admitted to sharing any form of disinformation in the past month, either knowingly or unknowingly; they share [political news](#) on social media at least once a day and have checked social media every day across three or more platforms. They also use social media to stay up-to-date with the news.

People who didn't fall into the super-sharer category were statistically much less likely to have shared COVID-19 disinformation.

When examining the data from all respondents across the five countries, those who had seen COVID-19 disinformation were more likely to believe that it affects trust in scientists, experts and health policies "to a great extent."

Professor Kate Daunt, who led the analysis, said: "Our research provides insights into the factors that make a person more likely to share disinformation about COVID-19, as well as the central role social media plays in people's lives."

The research also shows a third (31%) of those from the UK who had shared COVID-19 disinformation and fake news in the past admitted to having "unknowingly" shared "news" on [social media](#) that seemed accurate at the time of posting but they later discovered was

"exaggerated." Italy had the lowest percentage at 20%.

By contrast, the largest percentage of sharers of coronavirus disinformation and fake news who had "knowingly" shared "exaggerated" content was in Spain (31%) compared to the smallest group (11%) in Italy.

UK citizens were most likely to "never" fact check news before sharing it with others (28%). Italian citizens were most likely to "always" fact check (47%).

The UK also had the lowest percentage of people who said they had seen fake news relating to COVID-19—at 51%. Spain had the highest at 87%, with Italy at 84%, France at 72% and Germany at 58%.

Professor Daunt added: "There are distinct differences in terms of how people in these five European countries identify and understand fake news. There was a [significant relationship](#) in all countries between people who had not seen COVID-19 disinformation and those who "never" fact check. It's therefore highly likely that while the UK had the lowest percentage of people who said they had seen fake [news](#) online, a much higher number may have been exposed to disinformation without realizing it."

The study involved 3,696 citizens from France, Germany, Italy, Spain and the UK (700+ people per country), who were surveyed about [disinformation](#) and [fake news](#) between 18 March—30 April 2020.
