

Gentoo penguins are four species, not one, say scientists

November 3 2020

South Georgia Gentoo penguins (*P. poncetii*) live in more northerly habitats where conditions are milder, than their Southern Gentoo cousins which live on the Antarctic ice. Credit: Gemma Clucas

Gentoo penguins should be reclassified as four separate species, say scientists at the Milner Centre for Evolution at the University of Bath, after analysing the genetic and physical differences between populations around the southern hemisphere.

The researchers say that counting them as four separate species will aid in their conservation because it will make it easier to monitor any decline in numbers.

Gentoo penguins, with the Latin name *Pygoscelis papua*, live in a range of latitudes in the [southern hemisphere](#) and are currently split into two subspecies, *P. p. ellsworthi* and *P. p. papua*.

The researchers suggest these two sub species should be raised to species level and two new species created, which they have named *P. poncetii* after the Australian seabird conservationist Sally Poncet, and *P. taeniata* in recognition of a former proposal for this name dating to the 1920s.

Their study, published in the journal *Ecology and Evolution*, looked at the genomes of populations living in the Falkland Islands and South Georgia in the southern Atlantic Ocean, the South Shetland Islands in the Antarctic and Kerguelen Islands in the Indian Ocean.

They used genome data to create an evolutionary tree to understand the relationship between the different populations. When they combined these data with measurements of museum specimens from each of the populations, they found clear morphological (physical) and [genetic differences](#) between the four populations.

The four species of Gentoos look very similar, but do not interbreed and have adapted to live in significantly different habitats. Credit: Gemma Clucas

Dr. Jane Younger, Prize Fellow from the Milner Centre for Evolution at the University of Bath, led the study. She said: "For the first time, we've shown that these penguins are not only genetically distinct, but that they are also physically different too.

"Gentoos tend to stick close to their home colonies, and over hundreds of thousands of years have become geographically isolated from each other to the point where they don't interbreed with each other, even though they could easily swim the distance that separates them.

"The four species we propose live in quite different latitudes—for

example *P. ellsworthi* lives on the Antarctic continent whereas *P. poncetii*, *P. taeniata* and *P. papua* live further north where conditions are milder, and so it's not that surprising that they have evolved to adapt to their different habitats."

Ph.D. student Josh Tyler said: "They look very similar to the untrained eye, but when we measured their skeletons we found statistical differences in the lengths of their bones and the sizes and shape of their beaks.

"It's a similar story to giraffes, which were revealed in 2016 to be four genetically [distinct species](#)."

Northern Gentoos live on the Falkland Islands in the Southern Atlantic Ocean.

The scientists say that regarding the four populations as separate [species](#), gives conservationists a better chance of protecting their diversity because if there's a decline in one of them it will change the threat status as defined by the IUCN Red List.

Dr. Younger said: "Currently [gentoo penguins](#) are fairly stable in numbers, however there is some evidence of the northern populations moving further south as the climate gets warmer, so we need to watch them closely."

The proposed changes to the classification of gentoos will be reviewed by an international committee of scientists which will assess all the evidence in the scientific literature before the new taxonomy is accepted.
