

Within a hair's breadth—forensic identification of single dyed hair strand now possible

December 9 2020

How to distinguish the difference among artificially colored hairs?

Surface-enhanced Raman scattering (SERS) analysis

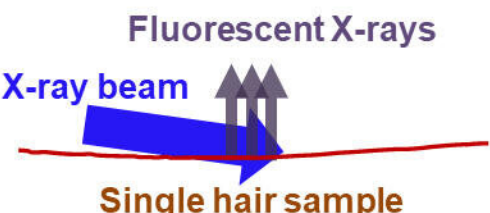

Laser beam
SERS signals

Single hair sample

X-ray fluorescence (XRF) analysis

Fluorescent X-rays
X-ray beam

Single hair sample

- The difference among hair dyes used for hair coloring can be identified by SERS analysis.
- Information about metallic elements originating from a hair dye product used for coloring can be obtained by XRF analysis.

- **A combination of these analytical methods makes it possible to distinguish the difference among hairs dyed by different hair dye products.**
- **This combination can be used for individual identification, and it can be applied to forensic investigation.**

An overview of the analytical techniques used in this study, which together make it possible to distinguish between two single strands of colored hair. Credit: Shinsuke Kunimura from Tokyo University of Science

In crime scene investigations, a single strand of hair can make a huge difference in the evolution of a case or trial. In most cases, forensic scientists must look for clues hidden in minuscule amounts of substances or materials found at crime scenes. If a fallen strand of hair with root cells attached is found, a DNA test can reveal the identity of a criminal; unfortunately, this seldom happens. Even though other types of DNA analysis can be conducted using the mitochondrial DNA embedded in the hair shaft itself, such tests are not sufficient to reliably identify a person and usually call for additional evidence.

But what if a bit of fashion consciousness could inspire a new forensic technique? In a recent study published in *Analytical Sciences*, scientists at the Tokyo University of Science, Japan, developed a strategy for identifying criminals from a single strand of [hair](#), leveraging the fact that hair dyes are becoming increasingly common. Their approach involves finding out if two individual strands of hair belong to the same person based on the composition of hair dye products found on them. To do this, they employed two well-known analytical methods: surface-enhanced Raman spectroscopy (SERS) and X-ray fluorescence (XRF) analysis.

Raman spectroscopy is an analytical technique based on the physical phenomenon of Raman scattering, which models certain energetic interactions that occur when photons collide with matter. SERS is a special type of Raman spectroscopy that provides a "structural fingerprint" of a material even when very few molecules are present in the target sample. On the other hand, XRF analysis involves irradiating a material with X-rays and examining the energies of photons re-emitted when the electrons in the sample leave the excited states. XRF analysis is especially useful to determine which metallic elements are present in a material.

The scientists conducted SERS and XRF analyses using [portable devices](#)

to see if they could distinguish between single strands of hog hairs dyed with different products. Associate Professor Shinsuke Kunimura, who led the study, explains why both analytical methods had to be used in combination, "SERS can easily detect the overall differences in composition between different types of hair dyes, such as permanent, semi-permanent, or natural dyes. However, it is not enough to distinguish between hair coloring products that contain or produce similar dyes. To do this, we also relied on XRF analysis, which can detect the presence of metallic elements used in the ingredients of hair dye products." Using both techniques, the scientists were able to easily distinguish between five different dyes applied to individual strands of hog hair.

Because both [analytical methods](#) used are almost non-destructive, the strategy proposed in this study could be used to quickly analyze hairs found in [crime scenes](#) on-site before they are sent for DNA analysis. "Our approach provides supportive information for more reliably identifying whose hair was found in a crime scene," remarks first author Momona Horiguchi. "This could help us clarify if someone is a criminal, meaning that our methodology could greatly contribute to forensic investigations."

Overall, this study showcases how analytical tools normally used in chemistry and materials science can be creatively adapted to vastly different fields, such as forensic investigations. Hopefully, in the future, it will prevent criminals from escaping by a hair's breadth!
