

(HMFL) of the Chinese Academy of Sciences (CAS) reported their new discovery recently with the help of the solution Nuclear Magnetic Resonance (NMR) technology.

"Our work is the first to display a dynamic trimolecular G-quadruplex (tri-GQ)," said Zhang Na, who led the team. "It is solely assembled through the self-trimerization of d(GTTAGG), preferentially in Na⁺ solution tolerant to an equal amount of K⁺ cation."

This examined sequence d(GTTAGG) could be regarded as either a reading frame shifted single repeat of human telomeric DNA, which is tightly related to cancer and aging, or a 1.5 repeat of *Bombyx mori* telomeric DNA.

The team demonstrated how eight guanines from three asymmetrically folded strands of d(GTTAGG) organized into a two-tetrad core, which featured a broken G-column and two width-irregular grooves.

To their surprise, they found that the well-ordered tri-GQ of d(GTTAGG) is not a static [structure](#). "It is a dynamic assembly having a life with constant movement." Zhang Na said excitedly, "this dynamic phenomenon is particularly suitable for an NMR study."

Fast strand exchanges on a timescale of second at 17°C spontaneously occur between folded tri-GQ and unfolded single-strand of d(GTTAGG) that both species coexist in dynamic equilibrium. Credit: XU Suping

Two-dimensional rotating frame overhauser effects spectroscopy (ROESY) spectrum verified that fast strand exchanges on a timescale of second at 17°C spontaneously occurred between folded tri-GQ and unfolded single-strand of d(GTTAGG) that both species coexist in dynamic equilibrium.

The polymorphism has been thought as an inherent feature for GQs. This demonstration will make GQ structures even more diverse with potentially more functional applications.
