

Intensified droughts will affect nitrogen emissions in rainfed agriculture

NO and N₂O are major contributors to atmospheric pollution, and agriculture is a major source of both. Seasonal variation of precipitation input can affect plant growth, soil microbial activities, and emissions of NO and N₂O. However, the complexity of the mechanisms and the temporal and spatial variations related to the emissions of NO and N₂O

in rainfed ecosystem are unclear.

Recently, a research team led by Prof. Fang Yunting from the Institute of Applied Ecology (IAE) of the Chinese Academy of Sciences (CAS) used a fully automated system to continuously measure soil NO and N₂O emissions for two years in a typical rainfed maize field in Northeast China.

The studies were published online in *Environmental Pollution* and *Frontiers in Environmental Science*, respectively.

Two years measurements revealed substantial interannual and [seasonal variations](#) for N gaseous emissions, especially the NO loss.

The researchers found that annual NO emissions differ strongly between the two years, with 8.9 kg N ha⁻¹ for the first year and 2.3 kg N ha⁻¹ for the second year, accounting for 5.9% and 1.9% of the applied fertilizer N, respectively. This difference was mainly attributed to the variations in the timing and amount of precipitation before and after the fertilization.

Additionally, they found that the severe spring drought affects [plant growth](#), soil NH₄⁺ and NO₃⁻ availabilities, and NO and N₂O emissions. During growing season, the temporal pattern of NO and N₂O emissions were similar, and mainly controlled by soil mineral N content and soil temperature. Both NO and N₂O emissions during the freeze–thaw periods were negligible in this region for rainfed agriculture.

Rainfed agriculture is one of the most common farming practices in Northeast China. With the [global climate change](#), [severe drought](#) makes the rainfed agriculture more vulnerable. The findings try to fill the gap in the understanding of climate change impacts on NO and N₂O emissions in rainfed agricultures (major cropping practices). They offer some advice to control the adverse effects of agricultural managements to

regional and global atmospheric pollution.
