2021 was one of the seven warmest years on record, according to six leading international datasets consolidated by the World Meteorological Organization (WMO), despite average global temperatures being

temporarily cooled by successive La Niña events at either end of the year.

The HadCRUT5 dataset is compiled by the Met Office and the University of East Anglia, with support from the National Centre for Atmospheric Research. HadCRUT5 is the most recent dataset to report its global findings for 2021. It shows that the year was  $0.76 \pm 0.04$  degrees Celsius above the 1961–1990 average, placing it joint sixth warmest (with 2018).

When compared with the pre-industrial global reference period, the year was  $1.1 \pm 0.1$  degrees Celsius above the 1850–1900 average. This aligns extremely well with figures already published by other international centers.

## **Authoritative assessment**

The WMO uses six international [data sets](#) to provide an authoritative assessment of global temperature change. They reported that 2021 was around  $1.11 \pm 0.13$  degrees Celsius warmer than the 1850–1900 average based on an average of the six data sets. 2021 is the 7th consecutive year (2015–2021) where global temperature has been over 1.0 degrees Celsius above pre-industrial levels, according to all datasets used by WMO.

The ranking of individual years often hinges on small or marginal differences between years and can vary slightly between data sets. Long term warming however is clear. Since the 1980s, each decade has been warmer than the previous one and this is expected to continue.

The warmest seven years have all been since 2015, with 2016, 2019 and 2020 in the top three. An exceptionally strong El Niño event occurred in late 2015 and continued into early 2016.

Dr. Colin Morice, of the Met Office, said: "2021 is one of the warmest years on record, continuing a series of measurements of a world that is warming under the effects of greenhouse gas emissions. This extends a streak of notably warm years from 2015 to 2021—the [warmest](#) seven years in over 170 years of measurements."

Prof Tim Osborn, of the University of East Anglia, said: "Each year tends to be a little below or a little above the underlying long-term [global warming](#). Global temperature data analyzed by the Met Office and UEA's Climatic Research Unit show 2021 was a little below, while 2020 had been a little above, the underlying warming trend. All years, including 2021, are consistent with long-standing predictions of warming due to human activities."

"Back-to-back La Niña events mean that 2021 warming was relatively less pronounced compared to recent years. Even so, it was still warmer than previous years influenced by La Niña. The overall long-term warming as a result of greenhouse gases is now far larger than the year-to-year variability caused by naturally occurring climate drivers," said WMO Secretary-General, Prof. Petteri Taalas.

Global [warming](#) and other long-term climate change trends are expected to continue as a result of record levels of heat-trapping greenhouse gases in the atmosphere.
