Research shows that historically, large-scale events such as World War II, the Great Depression, the 2008 recession and the SARS and N1H1 epidemics have impacted children's developmental trajectories with long-

lasting effects. In 2020, the COVID-19 pandemic created global school closures and severe disruption to education systems. The first study to examine the impact of the COVID-19 pandemic on preschoolers' educational development across different socioeconomic settings in Uruguay was recently published in *Child Development* by researchers at the Universidad de la República at Montevideo. The study showed the harmful effects of the disease outbreak on children's cognitive and motor skills.

"Early math and literacy performance are strong predictors of academic outcomes in primary school, and they may be the most difficult to compensate at home for because they require teaching expertise, appropriate activities and materials, and quality stimulation from caregivers," said Alejandro Vásquez-Echeverría, professor at the Universidad de la República and co-director of the Interdisciplinary Center of Cognition for Education and Learning (CICEA). "Losses were uneven across developmental areas with the largest deficits being in motor, language and logical-mathematical skills."

The study compared two groups of four- to six-year-old Uruguayan [children](#): one group of 34,355 children who attended preschool from 2018-2019 before the [pandemic](#) and the other group featuring 30,158 children who attended preschool during 2019-2020 (impacted by the COVID-19 pandemic). Researchers used longitudinal information from the Uruguayan School Readiness-Child Development Inventory, data collected through a developmental assessment of public-school children. The data collected did not include information about ethnicity.

Rather than using parental reports or online education platforms, children were assessed by teachers twice in age four classrooms and once by the end of age five. Teachers observed and rated a child's frequency of specific cognitive, motor, and socioemotional developmental behaviors during a typical school day within a period of three to four

weeks.

Researchers found that during the pandemic, the cognitive and motor development skills of children at age five suffered the most followed by their attitudes towards learning. Stay-at-home measures also led to a drastic decrease in physical activity which may explain the underdevelopment in [motor skills](#). Avoidant and anxious behaviors in children could be an indirect result of increased parental stress, or increased teacher stress. An unexpected finding was that the COVID cohort exhibited less aggressive behaviors when compared to the control group. School reopening conditions in Uruguay could explain this as this cohort had a lower child-teacher ratio and increased supervision of social interactions.

"Losses among children from more privileged schools were less pronounced," said Meliza Gonzalez, researcher at the Universidad de la República. "Relatedly, children who had already been struggling at age four classrooms displayed larger developmental losses, thus increasing the achievement gap. The findings can directly inform public policy by targeting interventions at children at greater risk. This is particularly relevant to educational achievement since [cognitive skills](#) during the transition from preschool to [primary school](#) are predictors of later academic outcomes, a phenomenon that is studied under the concept of 'school readiness'."

The authors acknowledge several limitations to the study. They cannot be certain of what aspects of the COVID-19 pandemic specifically impacted school readiness, could not account for family variables such as income, or others related to how they coped with schooling strategies at home. Teachers' assessments may have been biased because of, for example, shifts in their perception of expected behaviors due to the pandemic. The current study may not generalize to other contexts, as characteristics of [school](#) closures, mitigation measures, and other

COVID-19 related socioeconomic impacts differed across regions. The impact may have been underestimated due to vulnerable children dropping out from the COVID cohort. Given the limited evidence on developmental losses and its relevance for educational policies, it would be beneficial to conduct similar research in other cultural contexts.
