One of the major challenges in particle physics is how to interpret large data sets that consist of many different observables in the context of models with different parameters.

A new paper published in *EPJ Plus*, authored by Ursula Laa from the Institute of Statistics at BOKU University, Vienna, and German Valencia from the School of Physics and Astronomy, Monash University, Clayton, Australia, looks at the simplification of [large data sets](#) and many parameter problems using tools to split large parameter spaces into a small number of regions.

"We applied our tools to the so-called B-anomaly problem. In this problem there is a large number of experimental results and a theory that predicts them in terms of several parameters," Laa says. "The problem has received much attention because the preferred parameters to explain the observations do not correspond to those predicted by the standard [model](#) of [particle physics](#), and as such the results would imply new [physics](#)."

Valencia continues by explaining the paper shows how the Pandemonium tool can provide an interactive graphical way to study the connections between characteristics in the observations and regions of parameter [space](#).

"In the B-anomaly problem, for example, we can clearly visualize the tension between two important observables that have been singled out in the past," Valencia says. "We can also see which improved

measurements would be best to address that tension.

"This can be most helpful in prioritizing future experiments to address unresolved questions."

Laa elaborates by explaining that the methods developed and used by the duo are applicable to many other problems, in particular for models and observables that are less well understood than the applications discussed in the paper, such as multi-Higgs models.

"A challenge is the visualization of multidimensional parameter spaces; the current interface only allows the user to visualize high dimensional data spaces interactively," Laa concludes. "The challenge is to automate this, which will be addressed in future work, using techniques from dimension reduction."
