

# Hydrology controls lithium isotopes in rivers and seawater

June 23 2022, by LI Yuan

High-resolution river water  $\delta^7\text{Li}$ ,  $^{87}\text{Sr}/^{86}\text{Sr}$ , and hydrometeorological data from the NE Tibetan Plateau. Weekly variations of  $\delta^7\text{Li}$  and  $^{87}\text{Sr}/^{86}\text{Sr}$  in the carbonate-dominated BH (a) and silicate-dominated SL (b) catchments (Supplementary Fig. 2) along with daily  $Q_w$  and precipitation, showing inverse trends between  $\delta^7\text{Li}$  and  $Q_w$  in each river. When plotting up weekly data from the two rivers together (c), there is still an overall negative relationship, highlighting a strong hydrology control on riverine  $\delta^7\text{Li}$ . (d)  $^{87}\text{Sr}/^{86}\text{Sr}$  versus  $Q_w$ , showing large differences between the two rivers, reflecting their distinct lithology (Supplementary Fig. 3). The dashed lines in a and b represent ice-melting times. Errors for  $\delta^7\text{Li}$  are  $10^6$  years) and found that the dataset can be explained by a similar mechanism—shifts in the fluid residence time linked to changes in continental hydrology and the [water cycle](#).

The researchers showed, for the first time, that a hydrological control mechanism can explain all  $\delta^7\text{Li}$  records across various climatic transitions during the last ~445 million years, and led to a provocative conclusion: the Cenozoic seawater  $\delta^7\text{Li}$  record reflected overall drying of the continental climate over millions of years, rather than control by [tectonic uplift](#).
