

The importance of large pieces of wood in streams for land-based animals

June 22 2022, by Sean Nealon

Land managers have invested millions of dollars annually since the 1980s to place large pieces of wood back in streams, owing primarily to its importance for fish habitat. But little is known about how large wood in streams impacts birds and land-based animals.

Oregon State University scientists Ezmie Trevarrow and Ivan Arismendi

are beginning to change that with a just-published paper in *Biodiversity and Conservation* that outlines what they observed from one year of footage from motion-triggered [video cameras](#) they set up near multiple large log jams in a creek just west of Corvallis.

"This study reveals a hidden role of large wood in [streams](#)," said Trevarrow, who conducted the research as an undergraduate in the Honors College at Oregon State and is now a research associate at the University of Georgia. "The findings are valuable for land managers because they demonstrate additional value of restoration projects that involve wood placement into streams."

In the paper, Trevarrow and Arismendi focused their attention on what species they saw, the most common observed activities and the seasonality of the detections. Among their findings:

- Forty species were observed during the study period. The most [common species](#) included [mule deer](#), raccoon belted kingfisher, Townsend's chipmunk, [deer mouse](#) western grey squirrel, Virginia opossum and American robin.
- The most common animal activities around the log jams included movement (68%), rest (18%), and food handling/eating (9%), suggesting that large wood in streams acts as lateral corridors, or highways as Trevarrow put it, connecting land habitats year-round for wildlife.
- A strong seasonality in detections and [species richness](#) with the highest values occurring in summer and spring, and the lowest values in winter. For example, the most species were seen in summer (27), followed by spring (23), fall (22) and winter (16).

Before the 1970s, [land managers](#), recreationists, and the public considered large wood in rivers as undesirable, and the removal of wood from streams was extensively promoted across United States. Think of

European settlers and images of clean, flat rivers, Arismendi said.

"There is a lot of cultural legacy there, with log jams areas seen as places that increased flood risk, impeded navigation and transport, and accumulated debris" said Arismendi, an associate professor in the Department of Fisheries, Wildlife, and Conservation Sciences.

However, the scientific and managerial perception towards large wood in streams has changed.

While the benefits of large [wood](#) in streams for fish, particularly salmon, have been well studied, few studies have focused on the impact on land-based animals, the Oregon State researchers said.

For their study, they set up 13 cameras between June 2020 and June 2021 along Rock Creek, about 15 miles west of Corvallis. They collected 1,921 videos containing at least one animal detection, including some unexpected species and activities:

- A golden eagle, a species rarely seen in the region.
- Two mule deer being swept away after attempting to climb onto a log during a high flow event.
- A deer mouse and raccoon separately crossing a log jam during high flow even where water covered the full length of the log.

Arismendi is expanding the research this summer to Oregon State's H.J. Andrews Experimental Forest in the Cascades Mountains in Oregon with 30 motion-triggered camera sites.

"This is the beginning of looking into this topic more in-depth," Arismendi said. "I think there is a lot to unpack about the role of log jams in rivers."
